With a sample of 225.3 million  $J/\psi$  events taken with the BESIII detector, the decay  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  is analyzed. A structure at 1.84 GeV/c<sup>2</sup> is observed in the  $3(\pi^+\pi^-)$  invariant mass spectrum with a statistical significance of  $7.6\sigma$ . The mass and width are measured to be  $M = 1842.2 \pm 4.2^{+7.1}_{-2.6}$  MeV/c<sup>2</sup> and  $\Gamma = 83 \pm 14 \pm 11$  MeV. The product branching fraction is determined to be  $B(J/\psi \rightarrow \gamma X(1840)) \times B(X(1840) \rightarrow 3(\pi^+\pi^-)) = (2.44 \pm 0.36^{+0.60}_{-0.74}) \times 10^{-5}$ . No  $\eta'$  signals are observed in the  $3(\pi^+\pi^-)$  invariant mass spectrum, and the upper limit of the branching fraction for the decay  $\eta' \rightarrow 3(\pi^+\pi^-)$  is set to be  $3.1 \times 10^{-5}$  at a 90% confidence level.

97 Within the framework of Quantum Chromodynamics<sup>112</sup>  
98 (QCD), the existence of gluon self-coupling suggests that<sup>113</sup>  
99 in addition to conventional meson and baryon states,<sup>114</sup>  
100 there may exist bound states such as glueballs, hybrid<sup>115</sup>  
101 states and multiquark states. Experimental searches for<sup>116</sup>  
102 glueballs and hybrid states have been carried out for<sup>117</sup>  
103 many years, and so far no conclusive evidence has been<sup>118</sup>  
104 found. The establishment of new forms of hadronic mat-<sup>119</sup>  
105 ter beyond simple quark-antiquark system remains one<sup>120</sup>  
106 of the main interests in experimental particle physics. <sup>121</sup>

107 Decays of the  $J/\psi$  particle have always been regarded<sup>122</sup>  
108 as an ideal environment in which to study light hadron<sup>123</sup>  
109 spectroscopy and search for new hadrons. At BESII, im-<sup>124</sup>  
110 portant advances in light hadron spectroscopy were made<sup>125</sup>  
111 using studies of  $J/\psi$  radiative decays [1–3]. Of interest is<sup>126</sup>

the observation of the  $X(1835)$  state in  $J/\psi \rightarrow \gamma\pi^+\pi^-\eta'$  decay, which was confirmed recently by BESIII [4] and CLEO-c [5]. Since the discovery of the  $X(1835)$ , many possible interpretations have been proposed, such as a  $p\bar{p}$  bound state [6–9], a glueball [10, 11], or a radial excitation of the  $\eta'$  meson [12, 13]. In the search for the  $X(1835)$  in other  $J/\psi$  hadronic decays, BESIII reported the first observation of the  $X(1870)$  in  $J/\psi \rightarrow \omega\pi^+\pi^-\eta$  [14]. More recently, BESIII performed spin-parity analyses of threshold structures, the  $X(p\bar{p})$ , observed in  $J/\psi \rightarrow \gamma p\bar{p}$  [15], and the  $X(1810)$ , observed in  $J/\psi \rightarrow \gamma\omega\phi$  [16]. The spin-parity of the  $X(p\bar{p})$  is found to be  $0^{-+}$  and the  $X(1810)$  is confirmed to be a  $0^{++}$  state. To understand their nature, further study is strongly needed, in particular, in searching for new decay

127 modes.

128 Since the  $X(1835)$  was confirmed to be a pseudoscalar  
129 particle [4] and it may have properties in common with  
130 the  $\eta_c$ . Six charged pions is a known decay mode of the  
131  $\eta_c$ ; therefore,  $J/\psi$  radiative decays to  $3(\pi^+\pi^-)$  may be a  
132 favorable channel to search for the  $X$  states in the 1.8 -  
133 1.9  $\text{GeV}/c^2$  region.

134 In this letter, we present results of a study of  $J/\psi \rightarrow$   
135  $\gamma 3(\pi^+\pi^-)$  decays using a sample of  $(225.3 \pm 2.8) \times 10^6$   
136  $J/\psi$  events [18] collected with the BESIII detector [19].  
137 A structure at 1.84  $\text{GeV}/c^2$  (denoted as  $X(1840)$  in this  
138 letter), is clearly observed in the mass spectrum of six  
139 charged pions. Meanwhile in an attempt to search for  
140  $\eta'$  decaying into six charged pions, no  $\eta'$  signals are ob-  
141 served. The upper limit on the decay branching fraction  
142 is set at a 90% confidence level.

143 The BESIII detector is a magnetic spectrometer located at  
144 BEPCII [20], a double-ring  $e^+e^-$  collider with the design  
145 peak luminosity of  $10^{33} \text{ cm}^{-2}\text{s}^{-1}$  at a center of mass  
146 energy of 3.773 GeV. The cylindrical core of the BESIII  
147 detector consists of a helium-based main drift chamber (MDC),  
148 a plastic scintillator time-of-flight<sup>183</sup> system (TOF), and a  
149 CsI(Tl) electromagnetic calorimeter (EMC), which are all  
150 enclosed in a superconducting<sup>185</sup> solenoidal magnet providing  
151 a 1.0 T magnetic field.<sup>186</sup> The solenoid is supported by an  
152 octagonal flux-return<sup>187</sup> yoke with resistive plate counter  
153 muon identifier modules<sup>188</sup> interleaved with steel. The  
154 acceptance of charged<sup>189</sup> particles and photons is 93% over  
155  $4\pi$  solid angle, and<sup>190</sup> the charged-particle momentum  
156 resolution at 1  $\text{GeV}/c$  is<sup>191</sup> 0.5%. The EMC measures  
157 photon energies with the reso-<sup>192</sup>lution of 2.5% (5%) at  
158 1 GeV in the barrel (endcaps).<sup>193</sup>

159 Monte Carlo (MC) simulations are used to estimate<sup>194</sup>  
160 the backgrounds and determine the detection efficiency.<sup>195</sup>  
161 Simulated events are processed using GEANT4 [21, 22],<sup>196</sup>  
162 where measured detector resolutions are incorporated.<sup>197</sup>

163 Charged tracks are reconstructed using hits in the<sup>198</sup>  
164 MDC and are required to pass within  $\pm 10$  cm from the<sup>199</sup>  
165 interaction point in the beam direction and  $\pm 1$  cm in<sup>200</sup>  
166 the perpendicular plane to the beam. The polar angle<sup>201</sup>  
167 of the charged tracks should be in the region  $|\cos\theta| < 202$   
168 0.93. Photon candidates are selected from showers in the<sup>203</sup>  
169 EMC with the energy deposit in the EMC barrel region<sup>204</sup>  
170 ( $|\cos\theta| < 0.8$ ) greater than 25 MeV and in the EMC<sup>205</sup>  
171 endcap region ( $0.86 < |\cos\theta| < 0.92$ ) greater than 50<sup>206</sup>  
172 MeV. The photon candidates should be isolated from the<sup>207</sup>  
173 charged tracks by an opening angle of  $10^\circ$ .<sup>208</sup>

174 Candidate events are required to have six charged<sup>209</sup>  
175 tracks with zero net charge and at least one photon. All<sup>210</sup>  
176 the charged tracks are assumed to be pions. The candi-<sup>211</sup>  
177 date events are required to successfully pass a primary<sup>212</sup>  
178 vertex fit. A four-momentum constraint (4C) kinematic<sup>213</sup>  
179 fit is performed to the  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  hypothesis, and<sup>214</sup>  
180 the  $\chi_{4C}^2$  is required to be less than 30. If the number of<sup>215</sup>  
181 photon candidates is more than one, the  $\gamma 3(\pi^+\pi^-)$  com-<sup>216</sup>  
182 bination with the minimum  $\chi_{4C}^2$  is selected. To suppress<sup>217</sup>

FIG. 1. Distribution of the invariant mass of  $3(\pi^+\pi^-)$  from  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  events. The dots with error bars are data; the histogram is phase space events with an arbitrary normalization.

background events with multi-photons in the final states,  $P_{t\gamma}^2 = 2|\vec{P}_{\text{miss}}|^2(1 - \cos\theta_{\text{miss}})$  is required to be less than  $0.0004 \text{ GeV}^2/c^2$ , where  $\vec{P}_{\text{miss}}$  is the missing momentum of the six charged tracks and  $\theta_{\text{miss}}$  is the angle between the missing momentum and the momentum of the radiative photon. To further reject backgrounds with additional photons in the final state, the  $\chi_{4C}^2$  of four-constraint kinematic fit in the hypothesis of  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  is required to be less than that of the  $\gamma\gamma 3(\pi^+\pi^-)$  hypothesis, and the  $\gamma\gamma$  invariant mass in the  $\gamma\gamma 3(\pi^+\pi^-)$  hypothesis is required to be  $|M(\gamma\gamma) - M(\pi^0)| > 0.01 \text{ GeV}/c^2$ . To suppress background events with  $K_S \rightarrow \pi^+\pi^-$  in the final state,  $K_S$  candidates are reconstructed from secondary vertex fits to all oppositely charged track pairs. The invariant mass  $M(\pi^+\pi^-)$  must be within the range  $|M(\pi^+\pi^-) - M(K_S)| < 0.005 \text{ GeV}/c^2$ , where the  $M(K_S)$  is the nominal  $K_S$  mass [17]. The number of  $K_S$  candidates is required to be less than 2.

Figure 1 shows the  $3(\pi^+\pi^-)$  invariant mass spectrum for events that survive the above selection criteria, where a clear  $\eta_c$  peak is observed around  $2.98 \text{ GeV}/c^2$ , no evident  $\eta'$  signal is observed, and a distinct enhancement is seen around  $1.84 \text{ GeV}/c^2$ . In Fig. 2, the  $M(3(\pi^+\pi^-))$  distribution is plotted in the range  $[1.55, 2.15] \text{ GeV}/c^2$ .

To investigate possible backgrounds, we use a MC sample of 225 million simulated  $J/\psi$  decays, in which the decays with known branching fractions [17] are generated by BESEVTGEN [23] and unmeasured  $J/\psi$  decays by the Lundcharm model [24]. With the same selection criteria, we find no evident structure at  $1.84 \text{ GeV}/c^2$ . The background resulting from other, incorrectly reconstructed event topologies is mainly from  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$ , which show no structure at  $1.84 \text{ GeV}/c^2$  in the  $3(\pi^+\pi^-)$  mass spectrum. To estimate this contribution, we reconstruct the  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  decay from data and

FIG. 2. The fit of mass spectrum of  $3(\pi^+\pi^-)$ . The dots with error bars are data; the solid line is the fit result. The dashed line represents all the backgrounds, including the background events from  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  (dash-dotted line, fixed in the fit) and a third-order polynomial representing other backgrounds.

then re-weight the  $3(\pi^+\pi^-)$  invariant mass spectrum by a multiplicative weighting factor  $\varepsilon_1/\varepsilon_2$ , where  $\varepsilon_1$  and  $\varepsilon_2$  are the efficiencies for  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  MC events to pass  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  and  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  selection criteria, respectively. The selection criteria for  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  are similar to those applied to  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$  except for the requirement of an additional photon. The background analysis shows that the structure at  $1.84 \text{ GeV}/c^2$  in the  $3(\pi^+\pi^-)$  mass spectrum does not come from background events.

To extract the number of signal events associated with the peaking structure, an unbinned maximum likelihood fit is applied to the six pion mass spectrum. The fit includes three components: a signal shape, shapes for the  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  background and other backgrounds, which have the same final states, but not contribute to the structure around  $1.84 \text{ GeV}/c^2$ . The signal shape is described with a Breit-Wigner function modified by effects of the phase space factor and the detection efficiency, which is determined by a phase-space MC simulation of  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$ . The Breit-Wigner function is convolved with a Gaussian function to account for the detector resolution ( $5.1 \text{ MeV}/c^2$ , determined from MC simulation). For the background shape, the contribution from the  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  background, which is fixed in the fit and shown by the dash-dotted line in Fig. 2, is represented by the re-weighted  $3(\pi^+\pi^-)$  invariant mass spectrum, while other contributions are represented by a third-order polynomial. The total background is shown as the dashed line in Fig. 2.

The fit yields  $632 \pm 93$  events in the peak at  $1842.2 \pm 4.2 \text{ MeV}/c^2$  and a width of  $\Gamma = 83 \pm 14 \text{ MeV}$ . The statistical

significance of the signal is determined from the change in log likelihood and the change of number of degrees of freedom (d.o.f) in the fit with and without the structure  $X(1840)$ . Different possibilities have been studied by varying the fit range and the background shapes and by removing the phase space factor. Among all possibilities the smallest statistical significance was  $7.6\sigma$  corresponding to  $-2\Delta\ln L = 67$  and  $\Delta\text{d.o.f} = 3$ . With the detection efficiency,  $(11.5 \pm 0.1)\%$ , obtained from the phase space MC simulation, the product branching fraction is measured to be  $B(J/\psi \rightarrow \gamma X(1840)) \times B(X(1840) \rightarrow 3(\pi^+\pi^-)) = (2.44 \pm 0.36) \times 10^{-5}$ , where the error is statistical only.

No  $\eta'$  events are observed in the  $3(\pi^+\pi^-)$  mass spectrum. The upper limit at the 90% confidence level is 2.44 events with the confidence intervals suggested in Ref. [25]. The detection efficiency in the mass region  $[0.928, 0.988] \text{ GeV}/c^2$  is determined to be  $(7.8 \pm 0.1)\%$  from the MC simulation. Since only the statistical error is considered when we obtain the 90% upper limit of the number of events, the upper limit of the number of events is shifted up by one sigma of the total systematic uncertainty shown below in Table I. With the number of  $J/\psi$  events and the measured  $B(J/\psi \rightarrow \gamma\eta') = (5.16 \pm 0.15) \times 10^{-3}$  [17], the upper limit of the branching fraction is obtained to be  $B(\eta' \rightarrow 3(\pi^+\pi^-)) < 3.1 \times 10^{-5}$ .

Sources of systematic errors and their corresponding contributions to the measurement of the branching fractions are summarized in Table I. The uncertainties in tracking and photon detection have been studied [26] and the difference between data and MC is about 2% per charged track and 1% per photon, which is taken as the systematic error. Uncertainty associated with the 4C kinematic fit comes from the inconsistency between data and MC simulation of the fit; this difference is reduced by correcting the track helix parameters of MC simulation, as described in detail in Ref. [27]. In this analysis, we take the efficiency with correction as the nominal value, and take the difference between the efficiencies with and without correction as the systematic uncertainty from the kinematic fit. The background uncertainty is determined by changing the background functions and the fit range. The uncertainties from the mass spectrum fit include contributions from the variation of the phase space factor and the possible impact of other resonances (eg.  $f_2(2010)$ ). The systematic error for the  $P_{\gamma\gamma}^2$  selection criterion is estimated with the sample of  $J/\psi \rightarrow \pi^0 3(\pi^+\pi^-)$  by comparing the efficiency of this requirement between MC and data. For the detection efficiency uncertainty due to the unknown spin-parity of the structure, we use the difference between phase space and a pseudoscalar meson hypothesis. The uncertainties from MC statistics, the branching fraction of  $J/\psi \rightarrow \gamma\eta'$  [17] and the flux of  $J/\psi$  events [18] are also considered. We assume all of these sources are independent, and take the total systematic error to be their sum in quadrature.

The systematic uncertainties on mass and width are

306 estimated from the mass scale, background shape, fit-  
 307 ting range, mass spectrum fit, and possible biases due to  
 308 the fitting procedure. The uncertainty from the detector  
 309 resolution is checked by using a double Gaussian func-  
 310 tion as the resolution function, and the change is found  
 311 to be negligible. The uncertainty from the mass scale  
 312 is estimated by fitting the  $\eta_c$  resonance in  $M(3(\pi^+\pi^-))$   
 313 spectrum. Uncertainties from the background shape and  
 314 fitting range are estimated by varying the functional form  
 315 used to represent the background and the fitting range.  
 316 Uncertainties from mass spectrum fit include contribu-  
 317 tions from the variation of the phase space factor and  
 318 the possible impact of other resonances (eg.  $f_2(2010)$ ).  
 319 Possible biases due to the fitting procedure are estimated  
 320 from differences between the input and output of the  
 321 mass and width values from MC studies. Adding these  
 322 sources in quadrature, the total systematic error on the  
 323 mass is  $^{+7.1}_{-2.6}$  MeV/ $c^2$  and on the width is  $\pm 11$  MeV.

TABLE I. Summary of the systematic uncertainties in the  
 branching fractions (in unit of %).

Sources	$X(1840)$	$\eta'$
MDC tracking	12	12
Photon detection	1	1
$P_{t\gamma}^2$ cut	2.0	2.0
Kinematic fit	4.3	5.1
Background uncertainty	17.1	-
Mass spectrum fit	$^{+10.3}_{-20.3}$	-
Detection efficiency	6.1	-
MC statistics	0.9	1.3
$B(J/\psi \rightarrow \gamma\eta')$	-	2.9
Number of $J/\psi$ events	1.2	1.2
Total	$^{+24.6}_{-30.2}$	13.7

324 In summary, we studied the decay  $J/\psi \rightarrow \gamma 3(\pi^+\pi^-)$   
 325 with a 225.3 million  $J/\psi$  event sample [18] accumu-  
 326 lated at the BESIII detector. A structure at 1.84  
 327 GeV/ $c^2$  is observed in the  $3(\pi^+\pi^-)$  mass spectrum with  
 328 a statistical significance of  $7.6\sigma$ . Fitting the structure  
 329  $X(1840)$  with a modified Breit-Wigner function yields  
 330  $M = 1842.2 \pm 4.2^{+7.1}_{-2.6}$  MeV/ $c^2$  and  $\Gamma = 83 \pm 14 \pm 11$   
 331 MeV. The product branching fraction is determined to  
 332 be  $B(J/\psi \rightarrow \gamma X(1840)) \times B(X(1840) \rightarrow 3(\pi^+\pi^-)) =$   
 333  $(2.44 \pm 0.36^{+0.60}_{-0.74}) \times 10^{-5}$ . The comparison to the BESIII  
 334 results of the masses and widths of the  $X(1835)$  [4],  
 335  $X(p\bar{p})$  [15],  $X(1870)$  [14], and  $X(1810)$  [16] are displayed  
 336 in Fig. 3, where the mass of  $X(1840)$  is in agreement with  
 337 those of  $X(1835)$  and  $X(p\bar{p})$ , while its width is signifi-  
 338 cantly different from either of them. However, we do not  
 339 include the BESII result in Fig. 3 as a more precise study  
 340 of the  $X(1835)$  in BESIII [4] indicates that one must  
 341 consider the presence of additional resonances above 2  
 342 GeV/ $c^2$  that were not apparent in the BESII analysis  
 343 to obtain an accurate determination of the width of the  
 344  $X(1835)$ . Therefore, based on these data, one cannot

FIG. 3. Comparisons of observations at BESIII. The error bars include statistical, systematic, and, where applicable, model uncertainties.

determine whether  $X(1840)$  is a new state or the signal  
 of a  $3(\pi^+\pi^-)$  decay mode of an existing state. Further  
 study, including an amplitude analysis to determine the  
 spin and parity of the  $X(1840)$ , is needed to establish  
 the relationship between different experimental observa-  
 tions in this mass region and determine the nature of the  
 underlying resonance or resonances.

A search for  $\eta' \rightarrow 3(\pi^+\pi^-)$  is also performed, but no  
 $\eta'$  signal is observed. The upper limit on the branch-  
 ing fraction for the decay at the 90% confidence level is  
 $B(\eta' \rightarrow 3(\pi^+\pi^-)) < 3.1 \times 10^{-5}$ , which is improved by  
 one order of magnitude compared to the previous meas-  
 urement [28].

The BESIII collaboration thanks the staff of BEPCII  
 and the computing center for their strong support. This  
 work is supported in part by the Ministry of Science and  
 Technology of China under Contract No. 2009CB825200;
