The data deluge has arrived. Data-driven science is accelerating rapidly, but without the necessary social, technical, or policy infrastructure to support the capture, management, curation, use, and reuse of those data. Universities, libraries, funding agencies, and investigators are making critical decisions about what data to keep, in what form, for how long, and at what price. Academic programs are struggling to teach new skills in data management and policy, within the disciplines and within the information professions. All of these efforts are hampered by the lack of robust research that compares sites, disciplines, practices, and policies over a long period of time. The UCLA Knowledge Infrastructures Team studying data, data practices, and data curation brings to this problem several decades of research experience in the social studies of science, digital libraries, and information systems design and development. Related projects by each of the investigators are linked individually.

Responsibility

Publications are arguments made by authors, and data are the evidence used to support the arguments.

C.L. Borgman (2015). *Big Data, Little Data, No Data:* Scholarship in the Networked World. MIT Press

Responsibility

- Publications
 - Independent units
 - Authorship is negotiated
- Data
 - Compound objects
 - Ownership is rarely clear
 - Attribution
 - Long term responsibility: Investigators
 - Expertise for interpretation: Data collectors and analysts

hudsonalpha.org

Attribution of data

- Legal responsibility
 - Licensed data
 - Specific attribution required
- Scholarly credit: contributorship
 - "Author" of data
 - Contributor of data to this publication
 - Colleague who shared data
 - Software developer
 - Data collector
 - Instrument builder
 - Data curator
 - Data manager
 - Data scientist
 - Field site staff
 - Data calibration
 - Data analysis, visualization
 - Funding source
 - Data repository

A role for self-gravity at multiple length scales in the process of star formation

Alyssa A. Goodman^{1,2}, Erik W. Rosolowsky^{2,3}, Michelle A. Borkin¹†, Jonathan B. Foster², Michael Halle^{1,4}, Jens Kauffmann^{1,2} & Jaime E. Pineda²

Self-gravity plays a decisive role in the final stages of star formation, where dense cores (size -0.1 parsecs) inside molecular clouds collapse to form star-plus-disk systems'. But self-gravity's role at earlier times (and on larger length scales, such as ~1 parsec) is unclear; some molecular cloud simulations that do not include self-gravity suggest that 'turbulent fragmentation' alone is sufficient to create a mass distribution of dense cores that resembles, and sets, the stellar initial mass function'. Here we report a 'dendrogram' (hierarchical tree-diagram) analysis that reveals that self-gravity plays a significant role over the full range of possible scales traced by 13CO observations in the L1448 molecular cloud, but not everywhere in the observed region. In particular, more than 90 per cent of the compact 'pre-stellar cores' traced by peaks of dust emission' are projected on the sky within one of the dendrogram's self-gravitating 'leaves'. As these peaks mark the locations of already-forming stars, or of those probably about to form, a self-gravitating cocoon seems a critical condition for their existence. Turbulent fragmentation simulations without self-gravityeven of unmagnetized isothermal material-can yield mass and velocity power spectra very similar to what is observed in clouds like L1448. But a dendrogram of such a simulation' shows that nearly all the gas in it (much more than in the observations) appears to be self-gravitating. A potentially significant role for gravity in 'non-self-gravitating' simulations suggests inconsistency in simulation assumptions and output, and that it is necessary to include self-gravity in any realistic simulation of the star-formation process on subparsec scales.

Spectral-line mapping shows whole molecular clouds (typically tens to hundreds of parsecs across, and surrounded by atomic gas) to be marginally self-gravitating. When attempts are made to further break down clouds into pieces using 'segmentation' routines, some self-gravitating structures are always found on whatever scale is sampled." But no observational study to date has successfully used one spectral-line data cube to study how the role of self-gravity varies as a function of scale and conditions, within an individual region.

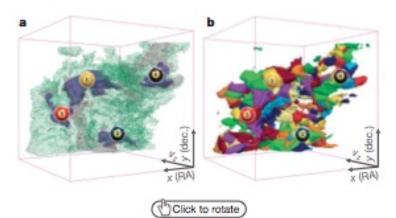

Most past structure identification in molecular clouds has been explicitly non-hierarchical, which makes difficult the quantification of physical conditions on multiple scales using a single data set. Consider, for example, the often-used algorithm CLUMPFIND? In three-dimensional (3D) spectral-line data cubes, CLUMPFIND operates as a watershed segmentation algorithm, identifying local maxima in the position—position—velocity (p-p-v) cube and assigning nearby emission to each local maximum. Figure 1 gives a two-dimensional (2D) view of L1448, our sample star-forming region, and Fig. 2 includes a CLUMPFIND decomposition of it based on ¹⁵CO observations. As with any algorithm that does not offer hierchically nested or

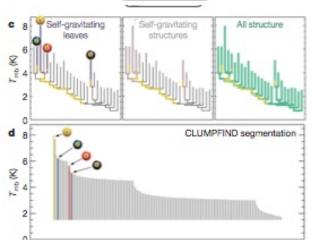

overlapping features as an option, significant emission found between prominent clumps is typically either appended to the nearest clump or turned into a small, usually 'pathological', feature needed to encompass all the emission being modelled. When applied to molecular-line

Figure 1 | Near-infrared image of the L1448 star-forming region with contours of molecular emission overlaid. The channels of the colour image correspond to the near-infrared bands J (blue), H (green) and K (red), and the contours of integrated intensity are from 13CO(1-0) emission*. Integrated intensity is monotonically, but not quite linearly (see Supplementary Information), related to column density ", and it gives a view of 'all' of the molecular gas along lines of sight, regardless of distance or velocity. The region within the yellow box immediately surrounding the protostars has been imaged more deeply in the near-infrared (using Calar Alto) than the remainder of the box (2MASS data only), revealing protostars as well as the scattered starlight known as 'Cloudshine'll and outflows (which appear orange in this colour scheme). The four billiard-ball labels indicate regions containing self-gravitating dense gas, as identified by the dendrogram analysis, and the leaves they identify are best shown in Fig. 2a. Asterisks show the locations of the four most prominent embedded young stars or compact stellar systems in the region (see Supplementary Table 1), and vellow circles show the millimetre-dust emission peaks identified as starforming or 'pre-stellar' cores'.

Documenting Data for Interpretation

Engineering researcher: "Temperature is temperature."

CENS Robotics team

Biologist: "There are hundreds of ways to measure **temperature.** 'The temperature is 98' is low-value compared to, 'the temperature of the surface, measured by the infrared thermopile, model number XYZ, is 98.' That means it is measuring a proxy for a temperature, rather than being in contact with a probe, and it is measuring from a distance. The accuracy is plus or minus .05 of a degree. I [also] want to know that it was taken outside versus inside a controlled environment, how long it had been in place, and the last time it was calibrated, which might tell me whether it has drifted.."

Incentives

- Publications that report the research Vs.
- Data that are reusable by others

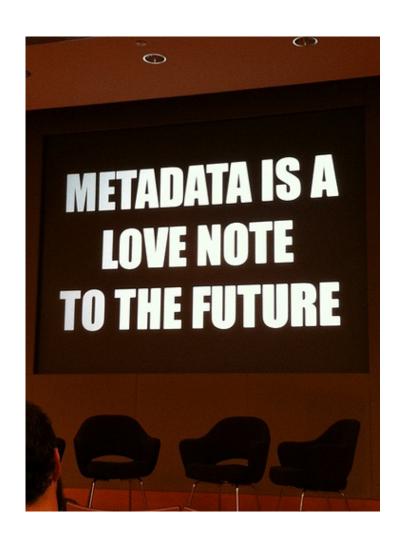

Pepe, A., Mayernik, M. S., Borgman, C. L. & Van de Sompel, H. (2010). From Artifacts to Aggregations: Modeling Scientific Life Cycles on the Semantic Web. Journal of the American Society for Information Science and Technology, 61(3): 567–582.

Metadata

- Metadata is structured information that describes, explains, locates, or otherwise makes it easier to retrieve, use, or manage an information resource.*
 - descriptive
 - structural
 - administrative

Provenance

- Libraries: Origin or source
- Museums: Chain of custody

 Internet: Provenance is information about entities, activities, and people involved in producing a piece of data or thing, which can be used to form assessments about its quality, reliability or trustworthiness.*

Q to explore in FaceBase community

- How do you assign credit and responsibility for data creation, curation, use, and reuse?
- How will you balance discipline/speciesspecific data models and policies with integrative models?
- What data do you expect you to share, with whom, how, and for how long?
- What scientific value do you expect to gain from sharing data via FaceBase?

Q to explore in FaceBase community

- Who invest in data curation, and at what stages of sharing and reuse?
- What is the scope of overlap between contributors and users of FaceBase data?
- What scientific value can users obtain from these data, with what kinds of investments?
