## AKNOWLEDGEMENTS

I would like to thank my family and friends who have become family. Dad, thank you for working countless hours selling cars to support me and teaching me the importance of working hard even when it was difficult. Mom, thank you for modeling the importance of literacy and education and motivating me to achieve in school. To my dear husband, who coordinated travel, alleviated the stress of medical bills and constantly encouraged me. Without your unwavering support the dream of completing a Ph.D. would be merely that, a dream.

I am incredibly grateful to my advisors at UC Irvine who nurtured my academic development and never waned in their support. George Farkas, thank you for taking me in as a late addition to your advisees. Your guidance and encouragement through all the milestones of the program is very much appreciated. Thad Domina, thank you for your willingness to always keep your door open and answer the infinite questions I posed. I learned a great deal from those unscheduled meetings that helped me keep momentum to keep moving forward. Anne McDaniel, although your time in Irvine was brief, your support did not go unnoticed. Thank you for persisting as a member of my committee from afar.

My dear friends, thank you for proofreading countless papers and consoling me when I doubted my abilities. To my C3 cohort members, who grew together both in friendship and knowledge during our five years in Irvine. A special thanks is necessary for my colleagues who kept writing and swimming dates with, they were both essential in the dissertation writing process. Thank you to the faculty and students at the UC Davis Center for Poverty Research, my visiting position there inspired me to continue researching policy areas to improve the lives of low-income young adults and formed meaningful friendships.

# ABSTRACT OF THE DISSERTATION 

Career and Technical Education Across Three Decades: 1982-2004

By<br>Mary Ellen Cashen<br>Doctor of Philosophy in Education<br>University of California, Irvine, 2014<br>Professor George Farkas, Chair

In this study, trends in career and technical education (CTE) course completion and their effects on post-secondary degree attainment, employment and earnings are analyzed using high school transcript data from HS\&B: 1982, NELS: 1992 and ELS: 2002. Findings show a decrease in overall career and technical education units completed that is largely driven by a decrease in such coursework by females in the 2002 cohort. Changes in the mean units of CTE coursework by type are discussed. I hypothesize that CTE will decrease the likelihood of a young adult enrolling in college, but increase employability and earnings. My analyses find a negative effect on later education; little effect on employability and mixed effects on earnings, with results based somewhat on the type of CTE completed. These findings cast doubt on whether CTE as presently implemented is worth its cost.

Keywords: Career and Technical Education, high school, sex differences, post-secondary education and earnings

## Chapter 1: Introduction

In the early 1900s, the United States economy required a large pool of skilled workers, which resulted in the growth of career and technical education (CTE) programs (Goldin \& Katz, 2000). Over time, economic pressure to increase educational attainment has resulted in increased numbers of high school students completing college preparatory coursework and attending college, a movement termed "College for All" (Rosenbaum, 2001). Concurrently, the federal government became increasingly involved in K-12 education and their policies influenced the "College for All" movement: A Nation at Risk in 1983, Goals 2000 in 1994, No Child Left Behind in 2001 and currently the Common Core State Standards (Domina \& Saldaña, 2012). No Child Left Behind imposed increased academic accountability in 2001 and the current adoption of the Common Core Standards has raised academic rigor consistently across states. These standards are a set of academically focused benchmarks in mathematics and English language arts developed by the National Governors Association and the Council of Chief State School Officers, currently being implemented in 43 states and the District of Columbia ${ }^{1}$.

Raised expectations for American high schools in the latter part of the century impacted curricular intensity (i.e. increased rigor in college-preparatory academic coursework), which has permeated every aspect of schools. American schools were tasked with educating all students to rigorous standards while combating mediocre scores on national and international exams (Ravitch, 2000). This forced the majority of students into academic tracks to prepare for college. However, one criticism of these initiatives is that business and industry had limited input, and as such, the standards reflect a narrow definition of academic proficiency with little attention paid

[^0]to specific skills and knowledge valued in the workplace (National Association of State Directors of Career Technical Education Consortium, 2010).

This notion of "College for All" in high schools has become increasingly apparent in the U.S. Department of Education's policy. This shift towards a rigorous academic curriculum reflects the 1983 National Commission on Excellence in Education recommendation that all high school students complete at least three full-year credits in mathematics, science and social studies and four full-year credits in English. As a result, the total number of academic courses taken by a typical high school graduate during four years of high school increased by $31 \%$ : from 12.9 credits in 1982 to 16.9 credits in 2000 (Bishop \& Mane, 2004). Analysis of nationally representative transcripts shows that high school students complete more rigorous academic course loads than ever before (Adelman, 2006). This resulted in a diminished focus on the other goals of high school.

Despite the curricular intensification, academic tracks are not the only high school curricular options; alternative pathways to high school graduation remain available to those students who pursue career training. Career and technical education (CTE) in U.S. high schools remains a large and complex enterprise. In 2002, high school students spent more than 1.5 billion hours in vocational courses of varying types. Courses in general labor market preparation, which include principles of technology, industrial arts, typing, keyboarding, etc., and family and consumer sciences are offered in almost every high school. High school graduates in 2000 took 1.2 full-year introductory CTE courses during high school (National Center for Education Statistics, 2003). In the same year, nearly $91 \%$ of graduates completed at least one occupation specific course, and $44 \%$ completed three or more courses (Levesque, 2003).

Common Core's substantial academic emphasis, alongside the curricular integration focus of Perkins IV poses a challenge for states, districts and schools to design CTE courses that effectively support core competencies in math and in English (Bozick \& Dalton, 2013). While increased academic requirements might have resulted in some students having less time to take CTE courses, students' predominant method for accruing additional academic credits seems to have been to increase the total number of credits they earned rather than to decrease CTE course completion. The average student completed 0.5 fewer units in CTE in 2000 than the average high school student in 1982, while completing 4 more units of overall high school coursework (National Center for Education Statistics, 2000).

Simultaneous to federal development in academic curriculum in high schools, CTE policy has also evolved since 1917, when the Smith-Hughes Act was passed. This legislation was based on Charles Prosser's Report of the National Commission to Aid on Vocational Education, which promoted vocational agriculture to train people and provided federal funds for this purpose (Stone \& Aliaga, 2007). This 1917 legislation is the basis both for the promotion of CTE, and for its isolation from academic curriculum in U.S. schools. The Vocational Education Act of 1963 was amended and reauthorized in the 1980s and 1990s; the federal government enacted several key pieces of legislation that impacted vocational education.

In 1984 the Carl D. Perkins Vocational and Technical Education Act was first authorized and subsequently reauthorized in 1988. In 1990 (Perkins II), 1994 (School-to-Work Opportunities Act) and in 1998 (Perkins III) career preparation in schools was supported through an integration of academic and vocational training (DeLuca, Plank \& Estacion, 2006). This legislation was initially implemented to strengthen and expand the economic base of the country, develop human resources, reduce structural unemployment, increase productivity, and strengthen
the Nation's defense capabilities by assisting the States to expand, improve, and update highquality programs of vocational-technical education. In the mid 1990s concerns arose with the school-to-work transitions in the U.S., stemming from the lack of connections between high school and work for the largest group of students who were completing comprehensive high school curricula. In 1994 the School to Work Opportunities Act (STWOA) was passed by Congress to address the following: the lack of connection between school and work that produced unmotivated young-adults with limited opportunities to move out of low-wage jobs; high school graduates who completed their education with insufficient skills for the labor market; and increased labor market demands for higher level thinking, teamwork and continued on the job learning (Neumark, 2007).

In addition to STWOA, the Perkins Act provided funding for vocational education, targeting specific populations of students: individuals with disabilities, individuals from economically disadvantaged backgrounds, individuals with limited English language proficiency and single parents. Essential to the most recent iterations of the Perkins legislation in 1998 and 2006 is the directive that occupational courses incorporate skills and concepts taught in core academic courses to increase the likelihood that CTE supports academic achievement (Bozick \& Dalton, 2013). In 2006, the reauthorized passage of the Perkins Act, commonly referred to as Perkins IV, reflected the most recent national commitment to prepare youth for the evolving challenges of the workplace through occupationally focused coursework. These goals have been updated, providing both a framework and funding to states and school districts to implement and maintain successful CTE. Notably, Perkins IV also renamed vocational education as career and technical education (CTE).

However, the goals of raising academic standards and improving workplace competencies are more competing than complementary. Academic and occupational programs frequently have different goals, students, faculty and separate areas of the school, making them unlikely to join forces. As Castellano et al. (2003) found, vocational and academic staff often do not know each other well, and are therefore less likely to collaborate with one another. Additionally, prior research suggests that vocational education has both positive and negative effects. On the positive side, CTE should enhance students' chances of finding employment as skilled workers and reduces their chances of slipping to the bottom of the occupational ladder. On the negative side, CTE has been reported to reduce the attainment of education beyond high school (Shavit \& Müller, 2000). Effects of these competing interests have been reported and discussed since at least the 1980s (National Commission on Excellence in Education, 1983; Secretary's Commission on Achieving Necessary Skills, 1991). The competing interests of U.S. high schools have recently been combined into an integrated model of college and career readiness for all high school graduates (Bozick \& Dalton, 2013; Smerdon \& Borman, 2012). Federal regulations impose increasingly rigorous academic course requirements and assessments intended to set high academic standards for all students (Adelman, 2006; Domina \& Saldaña, 2011; Ravitch, 2000; Rosenbaum, 2001). Despite efforts to prepare all students for college, American teens continue to pursue CTE coursework in high schools and community colleges, or forgo college altogether.

This concurrent course completion of both CTE and academic units occurred at a time when U.S. high schools were shifting away from prior methods of course assignment. During the mid-20th century, the majority of U.S. high schools were split into academic tracks that assigned students to college preparatory, honors, general and basic tracks (Lucas, 1999). This
tracking sorted students into homogeneous groups based on student's abilities and career goals (Rosenbaum, 1996). During this era, vocational tracks offered specialized courses to students with similar skills. These skills were honed and developed for particular career aspirations. Despite the potentially positive implications of CTE, the tracking of economically disadvantaged students into CTE and non-college preparatory coursework provides less access preparation for careers in science and mathematics and AP and honors-level courses (Blossfield, 1992; Geiser \& Santelices, 2006; Oakes, 1990). Consequently, beginning in the 1960s and 1970s the system of tracking was gradually dismantled nationwide (Moore \& Davenport, 1988). Schools continued to stratify coursework in each subject, but vocational students were no longer isolated with other work-bound students from their college-bound peers as they were in previous decades (Lucas, 1999; Rosenbaum, 1996).

Despite development in both academic and vocational curriculum in U.S. high schools in the 20th Century, a mismatch between the skills developed by American high school students and the skills required by high-wage employers emerged. Without more advanced skills, middle class jobs were inaccessible to low-skill workers (Murnane \& Levy, 1996). The wage gap between college graduates and both high school graduates and high school dropouts widened (Autor, Katz \& Kearney, 2005). Regardless of the concerns regarding post-secondary enrollment, proponents of high school CTE training argued the effect of CTE on the opportunities of the academically weak should not be judged against the odds of obtaining a college education (Arum \& Shavit, 1995).

## Chapter 2: Conceptual Framework and Literature Review

In this dissertation I build on Human Capital theory, which suggests high school coursework should result in real skills having measurable impacts on earnings and employability. Human Capital theory is based on the work of Becker (1975) and Mincer (1974); this theory explains both individuals' decisions to invest in human capital activities such as education and training, and the resulting pattern of individuals' lifetime earnings. Individuals' different levels of investment in education and training are explained in terms of their expected returns from an investment (Cellini, McKernan \& Ratcliffe, 2008). Human Capital theory implies school curricula have value because they impart skills that improve graduates productivity and wages in the labor market (Rose \& Betts, 2004). Investments in education and training such as CTE, entail costs in the form of both direct expenses and opportunity costs. Human capital theory can also explain the pattern of individuals' lifetime earnings. Early investment in human capital facilitates increasing financial benefits with age (Becker, 1975). Younger people have a longer remaining work life to benefit from their investment and their foregone wages are lower, so costs of investing are lower.

Based on the foundation that high school curricula impart skills that affect graduates productivity and wages in the labor market I analyze the changes and consequences of CTE course taking from high school graduates in 1982, 1992 and 2004. My work focuses not only on how types of CTE courses have changed over time, but how the completion of CTE coursework impacts college preparatory course completion. Furthermore, I investigate how enrollment in CTE courses changes over this time period by sex, family income and race/ethnicity. Finally, I build upon this to investigate the consequences of varying levels of CTE, as well as different types of CTE on labor market outcomes. The proposed study builds on Mane's 1999 study which
used NLS:72, HS\&B and NELS:88 to analyze trends in the payoffs to academic and vocational high school courses for non-college bound students. My research incorporates a new generation of survey data from ELS:2002. I use this new wave of data to analyze differences in CTE coursework for males and females and how over time different types of CTE coursework impact labor market outcomes.

## Literature Review

## Patterns in CTE Course Taking

Prior research suggests that students tend to be positioned on high school curriculum tracks that either put them on a path to post-secondary education or to immediate employment. For most students, the choice appears to be either/or, since work force preparation and college readiness are difficult to complete simultaneously (Kemple \& Willner, 2008). For decades, vocational education was distinguished by its isolation from both comprehensive and academic high school curricula (Hayward \& Benson, 1993). Thus, Stone and Aliaga (2007) found that only $5.9 \%$ of youth in the National Longitudinal Survey of Youth 1997 identified as both academic and CTE concentrators. However, the isolation of students completing vocational coursework was not without concern. In the 1980s and 90s perceptions arose over the academic skills of the American workforce, and that high school vocational education had become an "educational backwater" for disadvantaged and disabled students (U.S. Department of Education, 1994). Consequently, vocational education began to shift towards efforts to integrate academic and vocational skills in high school (Neumark, 2007). As a result of this integration, far fewer students are now tracked into any one program of study (Lucas, 1999).

Despite an overall reduction in high school students who focus on vocational training, over time, more high school students engaged in CTE coursework, while fewer had distinct CTE concentrations. Over 95 percent of high school students took at least one CTE course in 2000 (U. S. Department of Education, 2004), and nationally in the class of 2005 only $3 \%$ of students took no vocational classes or CTE units (Hudson \& Laird, 2009); however, from 1982-1998, the percentage of students who completed vocational concentrations of three or more courses in the same labor-market preparation domain decreased from 34\% to 25\% (National Center for Education Statistics, 2000). From 1982-2000, CTE course completion decreased slightly from 4.7 to 4.2 units (U. S. Department of Education, 2004). The decrease in vocational concentrators and frequency in which high school graduates took small amounts of vocational coursework is a logical consequence of the dismantling of school-wide systems of tracking (Moore \& Davenport, 1988). With the continued stratification of coursework by subject, vocational students were no longer isolated by track from their college-bound peers as they were in previous decades (Lucas, 1999; Rosenbaum, 1996).

Changes in the completion of vocational concentrations by U.S. high school students varied across the domains of CTE. The overall decline in the percentage of students completing a CTE concentration reflects the decline in the two largest vocational work forces: trade and industry, and business. The percentages of students concentrating in health care; technology and communications; food service and hospitality; and child care and education increased (National Center for Education Statistics, 2000). By 2003, changes had occurred differentially by CTE concentrations: course credit declines in business services, materials production, and mechanics and repair were offset by credit increases in health care, communication technology and computer technology (Levesque, 2003).

Historically, CTE has targeted mainly low-income and disadvantaged high school students (Lynch, 2000). There is an inverse relationship between family income and the number of CTE credits completed; students with the highest SES completed small amounts of CTE significantly more frequently than their lower SES peers, while low SES students predominated in completing high levels of CTE (Aliaga, Kotamraju \& Stone, 2014). Although students in the lowest quartile of SES completed three or more units of SES with much higher frequency than their peers in the highest quartile of SES, $49 \%$ and $33 \%$ respectively, CTE can no longer be said to serve exclusively low-income students, underperforming students or students from special populations (Aliaga, Kotamraju \& Stone, 2014).

## Effects of CTE

Some have argued that high school career and technical education is obsolete in our very technologically based, global economy. They argue that schools should concentrate on cultivating academic skills (Jacobs \& Grubb, 2003). Earlier work examined the impact of high school vocational education, finding little long-term economic benefit (Gustman \& Steinmeier, 1983; Meyer \& Wise, 1979; Neuman \& Ziderman, 1999). However, short-term benefits to CTE have been well documented. Vocational programs may also contribute to dropout prevention; students who complete CTE coursework typically have weaker academic backgrounds, and lower educational expectations than those on the academic track (Kelly \& Price, 2009). Evidence shows that vocational programs help keep these students in high school. Without vocational programs, more at-risk students would drop out of school each year than currently do (Kulik, 1998). In the 1980s, students with more than $20 \%$ of their coursework in CTE were more likely to graduate from high school (Arum, 1998). In the 1990s, increasing the number of CTE units a
student completed by 10th grade increased the likelihood of dropping out of high school (Ainsworth \& Roscigno, 2005). However, Plank (2001) found a contradictory result in which high school CTE positively impacted high school completion in 2000.

Despite positive impacts on dropout prevention, several researchers identify large negative effects of high school CTE on all types of post-secondary enrollment (Arum, 1998). In the 1990s, increasing the number of units of CTE that a student completed by 10th grade decreased the likelihood of attending a four-year college (Ainsworth \& Roscigno, 2005). With the continued growth in overall college attendance, the number of 18- to 24-year-olds increased from 28.0 million to 31.1 million between 2001 and 2011 , an increase of $11 \%$. The percentage of 18- to 24-year-olds enrolled in college rose from $36 \%$ in 2001 to $42 \%$ in 2011 (National Center for Education Statistics, 2013). This study seeks to determine if this finding continues to hold true in light of shifting federal policy to prepare high school students for colleges and careers. I also investigate the role CTE coursework serves in predicting educational attainment eight years after high school graduation.

Mane (1999) compares the short- and medium- run returns to vocational course taking for students who graduated high school in 1972, 1980, and 1992, and finds that these returns grew much higher after the 1970s. Bishop and Mane (2004) examine literature on the effects of secondary vocational education and also find evidence this return has been growing, possibly because the skill needs of business were growing and shifting very rapidly during the 1980s and 1990s, and because this type of education has become more effective.

Arum and Shavit (1995) argue while vocational education may inhibit future educational and occupational plans for some students, vocational education teaches students marketable skills and attitudes that can help them find skilled jobs and reduce their risk of unemployment or
employment as low paid, un-skilled workers. Bishop and Mane's analysis of NELS:92 data on high school graduates from 1992 and 1993 (including those who graduated in five years) indicates those who trained for specific occupations in high school were more successful in the labor market. These graduates spent more time employed (both immediately after high school and eight years later), worked better jobs and earned significantly more than students who did not take advanced CTE courses (Bishop \& Mane, 2004).

Both high school graduates who do not pursue further education and college dropouts are at an earnings disadvantage in their initial years in the labor market compared with those who obtained post-secondary CTE credentials. Studies show the average college graduate's earnings increase over their lifetimes, while adults who attain little more than a high school degree (or perhaps some college) have been experiencing stagnating wages (adjusted for inflation) across their lifetimes (United States Bureau of Labor Statistics, 2007). Some scholars argue it might be more advantageous to pursue other educational routes such as a two-year technical degree to develop skills that are readily applied to the higher-skilled labor force than completing some academic coursework at a post-secondary institution without completing a bachelor's degree (Kerckhoff, 2003; Rosenbaum, 2001).

Bozick and Dalton (2013), utilizing ELS: 2002 determined that most of the achievement differences between students who take a large number of occupational courses and students who take few or no occupational courses are due to preexisting differences between students before they enter high school, not the actual courses completed. Those who are high achievers gravitate to and/or are placed in academic courses, while low achievers gravitate to or are placed in CTE courses. With these selection processes operating long before students reach the end of high school, only a small effect can be attributed to courses completed (Bozick \& Dalton, 2013).

## Differential Effects of CTE for Female and Male High School Graduates

Experiences in early adulthood vary greatly by gender and highest level of education completed (Settersten \& Ray, 2010). Gender significantly predicts career choices across all career clusters, which partially explains the wide disparities in earnings and stratification of career choices based on gender (Nauta \& Epperson, 2003). There are distinct gender differences in occupational training, college majors and career choices that contribute to differential earnings potential (Fletcher \& Zirkle, 2009).

Historically, participation in the CTE track had varying effects on men and women. Forty years ago, women were routinely directed into traditionally female occupations like nursing, secretarial work, teaching and homemaker. While "male only" or "female only" labels are gone, gender roles remain (Sadker \& Zittleman, 2009). In 1977, girls made up 14\% of students in trade and industrial courses (National Women's Law Center, 2005). In 1990, girls outnumbered boys in home economics, health and secretarial courses while boys outnumbered girls in agriculture, trade, industry and technical fields (National Center for Education Statistics, 1991). In 2004, girls represented $15 \%$ of students taking classes in traditionally male, higher-paying fields such as carpentry, automotive, masonry and welding. More than $85 \%$ of females were clustered in traditionally female courses such as cosmetology, childcare, medical assistant, health aid and nursing (National Women's Law Center, 2005). Male and female high school students also completed disparate amounts of CTE coursework; $40 \%$ of males completed three or more CTE courses in comparison to $33 \%$ of females, while $24 \%$ of males completed one or fewer units in comparison to $29 \%$ of females (Aliaga, Kotamraju \& Stone, 2014). Additionally, CTE fields, which are nontraditional for their gender, have remained virtually unchanged since the 1970s
(United States Department of Education, 2004). The differences in high school CTE training by gender result in distinctly different employment opportunities with male dominated CTE fields paying an average wage of $\$ 20$, while female fields pay $\$ 15$ per hour (National Women's Law Center, 2005).

Arum and Shavit (1995) found that, regardless of gender, CTE had negative effects on post-secondary enrollment. Post-secondary enrollment overall also reflects differences by gender, however these gender differences have changed over time: from 1900 to 1930 male to female undergraduate enrollment in the U.S. was at about parity, however male enrollment increased in the 1930s and soared after World War II (Goldin, Katz, \& Kuziemko, 2006). The highpoint of gender imbalance occurred in 1947 when only $29 \%$ of the undergraduate population nation-wide was female (NCES, 2013). From 1947 on, female enrollment increased, especially in the 1970s (Goldin, Katz, \& Kuziemko, 2006). Gender equality occurred again in 1979 when $51 \%$ of the undergraduate population was female (NCES, 2013). Subsequently, women overtook men in undergraduate enrollment and graduation, with $57 \%$ of the undergraduate population being female in 2012 (NCES, 2013).

Differences in college enrollment rates reflect pre-existing gender differences from high school. Girls achieved considerably higher grades in high school than boys in the NLS:1972 and in NELS:1988 (Goldin, Katz, \& Kuziemko, 2006). Female high school seniors were more likely to have developed college plans, and reported some of the following perspectives: education is a vital investment, and knowledge that occupations they sought to pursue required a college education (Kleinfeld, 2009). In particular, women of color and low-SES participated in higher education at higher rates than their male counterparts. During the 1990s twice as many African American women as men earned college degrees (Lopez, 2003). Concurrently, there was a
substantial female lead in college graduation at all SES levels, but this gender gap was largest in the bottom of the SES distribution (Jacob, 2002). Kleinfeld's research revealed two concerning mindsets of high school boys: those from families with parents who graduated from college perceived higher education as expected and were rarely excited about college; while those boys from working class families had little knowledge of the job market, the likelihood of obtaining their "dream job" and the income necessary to live comfortable adult lives (2009). These findings provide evidence that something more is needed to engage young men in pathways to meaningful employment. Findings in the school-to-work literature show evidence that program participation is particularly advantageous for men in the forgotten-half with respect to both schooling and work-related outcomes. There are substantial benefits from such programs with targeted efforts towards male high school students whose characteristics and backgrounds make them less likely to attend college (Neumark, 2007). These programs can mediate the higher frequency of young men disliking school and lacking plans beyond high school that Kleinfeld identified (2009).

Over the past quarter-century, the earnings of women, unlike the earnings of men, have risen. Women's earnings have grown faster than those of men-although men have continued to out earn women. This is partially a result of women's wages were much lower to start; however, their average earnings have remained well below those of men. Nationally, women are concentrated in the jobs that cluster at the bottom of the income distribution (Blank, 1997). In 1975, a female high school graduate earned about $46 \%$ as much during the year as a male; by 2002, she earned $62 \%$ as much. As with men, the most educated women saw the largest earnings gains. In 1969 , only about $10 \%$ of men in their early thirties had wages that were below poverty level. By 2004, the share had more than doubled. Women fared a little better over the same time
span, but nearly half were still earning poverty-level wages by their mid-thirties (Danzinger, 2004).

## The Economy and Effects of the Recession of the Early 2000s

During the later part of the first decade of the 21st Century, the United States experienced a tremendous economic downturn. This recession produced a spike in unemployment, poverty and failed businesses; many people lost their jobs, homes and savings (Iceland, 2012). From December 2007 to October 2009, unemployment doubled from 5\% to $10 \%$ (Sahin, Song \& Hobijn, 2010). Household income inequality rose throughout this decade; there was a striking gap between those at the very top of the income distribution and the rest of society. For the first time since the 1960s the median household income decreased (Iceland, 2012). The effects of the recession varied by gender; in August of 2009 the unemployment rate for men was $11 \%$ while it was $8 \%$ for females. Job losses were concentrated in goods-producing industries of manufacturing and construction, which employ a higher proportion of male workers ( $71 \%$ and $88 \%$ male dominated respectively), while the health care and education sectors which employ a higher proportion of women increased during this time (23\% male) (Sahin, Song \& Hobijn, 2010). The faltering economy had dramatic consequences on wages and rates of employment that differentially affected men and women in the labor force during this time.

## Research Questions and Hypotheses

In order to understand the impacts of CTE for both males and females from these three graduating classes, I will conduct this study, which is based on the following questions:

1. Did U.S. high school graduates in 1982, 1992 and 2004 take different quantities and types of career and technical education? Did female and male U.S. high school graduates in 1982, 1992 and 2004 take different quantities and types of career and technical education?
2. What effect does high school career and technical education for graduates in 1982, 1992 and 2004 have on post-secondary educational attainment? Have these effects changed over time? What effect does high school career and technical education for graduates in 1982, 1992 and 2004 have on employment and earnings? Do these effects vary for different types of CTE coursework completed?
3. Are there differential effects of high school career and technical education for female and male high school graduates in 1982, 1992 and 2004 on post-secondary education? Are there differential effects of high school career and technical education for female and male high school graduates in 1982, 1992 and 2004 on employment and earnings?

In my research I expect to find that high school vocational education has negative impacts across cohorts on earnings. This hypothesis is based on previous research showing that high school vocational education has little long-term economic benefit (Gustman \& Steinmeier, 1983; Meyer \& Wise, 1979; Neuman \& Ziderman, 1999). Additionally, I expect to find that all types of high school CTE would have negative effects on post-secondary degree attainment across cohorts. This is based on previous work identifying large negative effects of high school

CTE on post-secondary enrollment (Ainsworth \& Roscigno, 2005; Arum, 1998; Arum \& Shavit, 1995). My final hypothesis is that males who complete CTE coursework in high school will earn more than their female counterparts because they are completing preparation for higher wage occupations. This is based on the findings about gender differences in labor market preparation and its effect on earnings from the National Center for Education Statistics, 1991; National Women's Law Center, 2005; and Sadker \& Zittleman, 2009. I believe CTE training will mediate some of the negative effects of a downturn in the economy for young men.

## Chapter 3: Data and Methods

In this study examining vocational course taking trends and post-secondary education and employment outcomes, I use three nationally representative surveys collected by the National Center for Educational Statistics (NCES), High School and Beyond (HS\&B), the National Educational Longitudinal Survey (NELS), and the Educational Longitudinal Survey (ELS). All three datasets include student surveys and transcript data that span high school cohorts from 1982-2004. HS\&B originally sampled approximately 30,000 high school sophomores in 1980, NELS began with 24,000 eighth graders in 1988 and ELS began with 18,000 high school sophomores in 2002. These data include student self-reports of family background, educational aspirations, school and work experiences, parent reports of educational attainment, as well as student high school transcripts. These samples include data from the 10th and 12th grade as well as ten years after high school graduation for HS\&B and eight years later for NELS and ELS.

In my analyses, I include variables that have been traditionally used for measuring participation in CTE, such as background characteristics, prior academic achievement, and academic performance in high school. Outcome variables include a categorical variable of highest level of education completed as ten years after high school graduation for HS\&B and eight years later for NELS and ELS. A continuous variable of annual earnings was collected ten and eight years after high school graduation respectively. This survey question asks participants to self-report their total earnings from the previous calendar year. Survey participants without data on their highest level of education or earnings were excluded from these analyses.

Using the Classification Scheme of Secondary School Courses (CSSC) based on the 2000 High School Transcript Study, the categories of CTE course completion are compared with transcript level data from all three datasets. Descriptive analyses are conducted to determine if
there are differences in the number of units in the following categories of CTE: technology and communication, health care, personal and other service, marketing and distribution, agriculture and renewable resources, business, trade and industry. All high school course work across data sets is measured in Carnegie units. A Carnegie unit is equivalent to a one-year academic course taken one period a day, five days a week (Ingels et al., 2007). I compare differences between cohorts in the total number of CTE units completed as well as differences in the number of units taken in each specific CTE category.

Students from the classes of 1982, 1992 and 2004 are identified as vocational and occupational concentrators based on the specifications from the 1998 revision of the Secondary School Taxonomy. Participants are identified as academic concentrators if they completed at least four Carnegie units of English, three of mathematics with at least one credit higher than algebra II, three credits of science with at least one credit in U.S. or world history and two credits in a single foreign language. The identification of academic concentrators across cohorts is particularly challenging because the curricular expectations of American high schools has changed dramatically in the decades since A Nation at Risk. The average class of 2004 high school graduate earned approximately 5 more academic credits than the average class of 1982 graduate, and the proportion of students completing the "New Basics" curriculum prescribed in $A$ Nation at Risk, increased from $2.32 \%$ in 1982, to $16.32 \%$ in 1992, and $31.92 \%$ in 2004 (Domina \& Saldaña, 2011). Occupational concentrators are identified across cohorts if they completed at least three credits in CTE.

## Methods

In this study, I first document the changes in the number of CTE courses completed by high school graduates in 1982, 1992 and 2004. Subsequently, I investigate the transformation in the types of CTE courses taken as the demands of employers change with technological advances. In this study I assess the effect of such coursework in high school on post-secondary education, employment and earnings. Later, the study focuses on the interaction between CTE course completion for male and female high school graduates. Variation in CTE course taking and its effects are evaluated based on the sex, class and race/ethnicity of the student.

I recoded high school coursework across datasets according to the CSSC, based on the 2000 High School Transcript Study. The National Center for Education Statistics (NCES) provides complete high school transcripts (as part of the High School Transcript study series) with standardized course credits, grades, and codes using the Classification of Secondary School Courses (CSSC) ${ }^{2}$. This recoding provides a coherent mechanism to compare course completion across the three decades documented in HS\&B, NELS: 88 and ELS: 2002. To maximize the comparability of the three graduating classes in my analyses, I use data only from on-time high school graduates from the HS\&B, NELS, or ELS 12th grade cohort for whom full transcript data were available, following the procedures outlined in Dalton et al. (2007). All analyses are weighted using the National Center for Education Statistics transcript data weights. All statistical analyses utilize the Stata "cluster" function to correct standard errors for the clustering of HSB, NELS and ELS respondents in high schools. This also controls for some of the differences in local course taking requirements.

[^1]My subsample for analysis includes only high school graduates with complete high school transcripts available in their respective dataset, since I relied heavily on the transcript data (rather than self-reports) to identify vocational concentration. It is important to note that by including only high school graduates in this analysis, it is possible that the findings reflect the course-taking histories of higher achieving students, since dropouts are more likely to be less academically proficient. In table 5 survey participants from each of the three datasets with transcript data are compared to survey participants who have transcript data and graduated from high school on time. On time graduates in my sub-sample for analysis included $80 \%$ of HS\&B, $82 \%$ of NELS and $78 \%$ of ELS survey participants. The subsample for analysis was slightly more White, Asian and female, and less Black, Hispanic and male than the complete samples of HS\&B, NELS and ELS. For NELS and ELS the sub-sample for analysis was slightly more female than male.

I categorize course taking patterns into three possible concentrations: college prep, vocational, and a general track for neither vocational nor college prep. Students who take three or more courses in CTE are considered vocational concentrators, and students who complete greater than zero and less than three Carnegie units of CTE are considered vocational samplers. For the longitudinal analysis, a college preparatory concentration is defined as taking: four credits of English, three credits of math, science, and social studies, as well as two years of foreign language ${ }^{3}$. Across the three cohorts there was a statistically significant increase in the percent of students whom completed college preparatory coursework over time; with 55\% of students completing college preparatory concentrations, high school graduates in 2004 were more likely to take some vocational coursework in high school while simultaneously completing

[^2]college preparatory coursework. Vocational and Academic tracks are no longer mutually exclusive routes to high school graduation. Student credit ratios measures the proportion of vocational to total credits to represent the proportion of vocational courses students take.

The highest level of education outcome variable was recoded to create fewer categories. Participants are identified as one of the following four categories: high school graduates with no additional education; high school graduates who completed some college or an associate's degree; bachelor's degree recipients and post-bachelor's certificate recipients; or participants who completed a master's or doctoral degree. Earnings data from all cohorts was recalculated using calculations from the Bureau of Labor Statistics ${ }^{4}$ (BLS) to account for inflation. All earnings are recalculated to reflect the equivalent of 2013 dollars, the most recent year that complete BLS data is available for.

Interaction variables were constructed to measure the interaction between sex and CTE behaviors. These interactions include: the interaction between the number of high school units completed and sex, the interaction between the percent of high school coursetime spent in CTE courses, and sex as well as interactions between sex and each category of CTE coursework.

[^3]
## Chapter 4: Results

## Changes in Career and Technical Education Course Taking

Table 1 provides descriptive statistics of on-time graduates from each of the three cohorts. This sample is slightly more White, Asian and female, and less Black, Hispanic and male than the complete samples of HS\&B, NELS and ELS. Over the three decades the subsample became more ethnically diverse, with more Black, Asian and Hispanic high school graduates surveyed. Both female and male high school graduates completed more total high school units in 2004 than in previous cohorts. The average high school graduate completed nearly four more Carnegie units in that year than in 1982. Concurrently, the total number of vocational or CTE units completed decreased by just over half a Carnegie unit. As a result of increased total high school course taking and decreased CTE course taking, the percent of vocational units completed by high school graduates in the three cohorts gradually decreased. Across the three decades, overall educational attainment increased, which is consistent with previous research (NCES, 2013). During that same time-period annual earnings decreased; this is likely a reflection of the overall decrease in full-time employment and increase in the completion of higher levels of education that keep young-adults out of the labor market until later in their twenties. This is particularly true for women, who across the three cohorts have surpassed their male counterparts in bachelor's and master's degrees. Seven years after graduation, $73 \%$ of female and $86 \%$ of male high school graduates from the class of 1992 had full-time jobs, while $64 \%$ of female and $77 \%$ of male high school graduates from the class of 2004 had full-time jobs. This may be a reflection of poor economic opportunities for young adults in 2011 when the 2004 graduates were seven years removed from high school, or it may be a reflection of their increasing commitment to education later in their twenties. With $26 \%$ of
females and $23 \%$ of males the class of 2004 enrolled in some form of education in 2011, this shows a 5\% increase for females and $1 \%$ increase for males in post-secondary enrollment from the 1992 cohort in 1999.

Table 1
Descriptive Statistics of On-time High School Graduates from the Three Cohorts, by Sex

|  | H\&SB: Class of 1982 |  |  |  | NELS: Class of 1992 |  |  |  | ELS: Class of 2004 |  |  |  |

| Earnings>0 | \$34,020 | 3,950 | \$44,500 | 4,080 | \$36,270 | 4090 | \$48,070 | 3670 | \$27,850 | 4250 | \$35,600 | 3750 |
| $\begin{aligned} & \text { Earnings>0 w/ } \\ & \text { FT Job } \end{aligned}$ |  |  |  |  | \$39,480 | 3040 | \$51,490 | 3100 | \$32,820 | 3050 | \$39,530 | 3000 |

Note. Weighted with NCES weights

Figure 1 illustrates the proportion of high school coursework focused on Career in Technical Education in the early 1980s, 1990s, and 2000s. This figure demonstrates that the course-taking patterns of American high school students changed over these decades. Graduates in 2004 were more likely to complete zero or less than three units of CTE than their predecessors. The 2004 cohort also completed less CTE coursework in proportion to their overall course completion.

Figure 1
Mean Number of CTE Units Completed by Cohort

Table 2 provides the mean number of total high school course units completed as well as the mean units in each CTE specialization for students who completed more than zero units in each particular course type. Additionally, the total number of students in each cohort who completed some of a particular course type is provided to demonstrate the likelihood that a student in each cohort might have been exposed to a specific CTE specialization. Notably, there was a $20 \%$ increase in total units completed across the three decades, and $15 \%$ decrease in CTE units completed. 1982 graduates completed a mean of 21.57 units, while in 1992 graduates completed 23.92 units and 2004 graduates completed 25.79 total high school units.

For students who completed any agriculture classes across the three cohorts, the mean number of agriculture units completed decreased steadily from 1982 to 2004. The number of survey participants who completed health courses increased from just over 400 in 1982 to over 1,000 in 2004 , which was accompanied by an increase in the mean number of health units completed. For students who completed any trade classes across the three cohorts, the mean number of trade units completed decreased by over half a unit from 1982 to 2004. During this time the percent of survey participants who completed any trade courses remained stable;
however those students were exposed to less classroom hours of trade instruction. The mean number of technology units completed increased from 0.88 to 1.09 from 1982 to 2004. During this time, there was a large increase in the number of high school graduates who completed technology coursework, with just over 1,000 completing technology classes in 1982 to over 7,000 in 1992 and nearly 6,000 in 2004. While only $2 \%$ of survey respondents in 1982 and 1992 and 5\% in 2004 completed military coursework, military course takers completed a mean of 1.41, 2.09 and 2.44 for each cohort respectively. In 2004, military units were higher proportionately than any other CTE specialization. Home economics/consumer home economics saw a decline in the mean number of courses completed across the three decades, however the number of high school graduates who completed such courses was high across cohorts, with a minimum of at least 4,800 in each of the three cohorts. In $1982,54 \%$ of survey completing students completed some business and marketing coursework. These students averaged 2.08 units of business and marketing in their high school career. By 2004, $56 \%$ of students completed some business and marketing, however they completed an average of 1.41 units, while completing more overall high school units.

Table 2
Mean Number of Courses Completed by CTE Specialization ${ }^{5}$

|  | HS\&B: 1982 |  |  | NELS: 1992 |  |  |  | ELS: 2004 |  |  |

|  | $M$ | $N$ | $\%$ | $M$ | $N$ | $\%$ | $M$ | $N$ | $\%$ |  |
| Total HS Units | 21.57 | 10,480 | $100 \%$ | 23.92 | 13,740 | $100 \%$ | 25.79 | 11,550 | $100 \%$ |  |
| Total CTE | 4.50 | 10,000 | $95 \%$ | 4.69 | 13,070 | $95 \%$ | 3.90 | 10,810 | $94 \%$ |  |
| General CTE | 1.31 | 7,960 | $76 \%$ | 1.24 | 2,910 | $21 \%$ | 1.33 | 4,300 | $37 \%$ |  |
| Agriculture | 2.06 | 800 | $8 \%$ | 1.93 | 1,160 | $8 \%$ | 1.81 | 1,050 | $9 \%$ |  |
| Health | 1.09 | 440 | $4 \%$ | 1.32 | 660 | $5 \%$ | 1.28 | 1,000 | $9 \%$ |  |
| Trade | 2.57 | 3,630 | $35 \%$ | 2.46 | 4,710 | $34 \%$ | 1.97 | 3,920 | $34 \%$ |  |
| Technology | 0.88 | 1,380 | $13 \%$ | 1.02 | 7,560 | $55 \%$ | 1.09 | 5,940 | $51 \%$ |  |
| Military | 1.41 | 190 | $2 \%$ | 2.09 | 250 | $2 \%$ | 2.44 | 530 | $5 \%$ |  |
| Home Ec \& Consumer | 1.56 | 4,890 | $47 \%$ | 1.43 | 6,060 | $44 \%$ | 1.34 | 4,860 | $42 \%$ |  |
| Business \& Marketing | 2.08 | 5,680 | $54 \%$ | 1.76 | 10,100 | $73 \%$ | 1.41 | 6,480 | $56 \%$ |  |

Note. Mean number of units for students who completed >0 units in a specific course with NCES weights, $N$ of survey participants and the \% of participants who completed each specific course type.

Figure 2 illustrates the percent of all surveyed students in each cohort who completed some coursework in each specialization. Across the three decades there is a dramatic decrease in the percentage of students who completed general CTE coursework. In 1982, 76\% of students completed some general CTE; this fell sharply in 1992 to $21 \%$ and remained relatively low in 2004 with $37 \%$ of students completing some general CTE. Additionally, from the 1982 cohort to the 1992 cohort there was a $42 \%$ increase in the percent of students completing technology coursework. This increase persisted in the 2004 cohort, with over half of all students completing some technology coursework. Although students completing health courses represent less than $10 \%$ of the population, there is a notable increase in the percentage of students completing health courses. In 1982 and 1992 only 4\% of students completed health courses, which doubled in 2004 to $9 \%$.

[^4]Figure 2
Percent of Students Participating in CTE by Type

Table 3 shows the mean units completed for participants who completed any amount of coursework in a particular concentration. Graduates who did not complete any coursework in a concentration were omitted from the mean to calculate the average for those who participated. There was an overall increase in high school units completed for both female and male students. The total number of CTE courses completed by high school graduates decreased over time, particularly for females in the 2004 cohort. Males completed more trade units than females across all three cohorts. Military unit completion increased steadily over time, but as illustrated in table 2 , served a relatively small population. Female students completed home economics and consumer home economics courses more frequently across the three cohorts. Females dominated business and marketing courses in 1982, but the completion of these courses by male graduates increased in 1992 and 2004 and was nearly even with females in the 2004 cohort.

Table 3
Mean Number of Units Completed by CTE Specialization for Female and Male participants who completed some coursework in a particular concentration

|  | HS\&B: 1982 |  | NELS: 1992 |  | ELS: 2004 |  |

Note. Average number of units for on-time high school graduates who completed $>0$ units in a specific course with NCES weights

## Effects of Career and Technical Education on Earnings

Figure 3 shows the distribution of inflation-adjusted earnings by number of vocational courses completed for each cohort of high school graduates. Across all three cohorts, graduates who completed fewer CTE courses earned more ten (HS\&B) and eight years (NELS \& ELS) after high school graduation. The 2004 cohort earned less than their predecessors in the 1992 cohort; much of this is likely attributable to the higher number of workers employed full-time and a smaller portion of the sample enrolled in post-secondary education eight years after high school graduation for the 1992 cohort as well as stagnating wages, which is particularly detrimental for the least educated.

Figure 3
Earnings of On-time High School Graduates by CTE Course Completion

## Effects of Career and Technical Course Completion on Post-Secondary Education

Table 6 presents odds ratio coefficients from multinomial logistic models measuring the effect of varying amounts and types of CTE on post-secondary educational attainment. The first equation uses background characteristics, total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed to predict educational attainment. The second model includes specific types of CTE courses to predict earnings to predict post-secondary attainment. Table 6 shows that increasing the percent of vocational coursework completed as a part of total high school coursework decreases the likelihood of completing all types of post-secondary education. This is significant and consistent across the three cohorts, and was found despite very extensive control variables, including math test scores. The completion of the majority of CTE course types decreased the likelihood of completing future education. This was true for all but health and technology coursework, which did not have adverse implications for completing further education beyond high school. This could be a result of high school graduates who are interested in health, pursuing further career training in entry level medical fields including nursing, phlebotomy, x-ray technicians or dental
assistants. Those students interested in technology have opportunities to pursue entry-level computer repair certificates or bachelor's level computer science degrees. Trade courses had smaller negative effects on completing some college, but these effects grew steadily larger for bachelor's, master's and doctoral degree attainment.

## Effects of Career and Technical Course Completion on Employment

Table 7 presents odds ratio coefficients from logistic regressions estimating the impact of varying amounts and types of CTE completion on the likelihood of having any type of employment nine (HS\&B) and seven (ELS \& NELS) years after high school graduation. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes specific types of CTE courses to predict employment. SES is a stronger predictor of employment for the class of 2004 than the classes of 1992 or 1982. This may demonstrate the power of family SES on employment when the economy is struggling as it was in 2011. Technology coursework had significant positive effects on employment for the class of 1982. For the class of 2004, the percent of vocational coursework completed in high school, general CTE and home economics/consumer home economics had significant negative consequences on employment.

Table 8 measures the impact of varying amounts and types of CTE completion on employment for one of the most vulnerable populations in the economy, high school graduates with no post-secondary coursework completed. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school
units completed. The third model includes specific types of CTE courses to predict employment. For the class of 1982 there was no significant effect of any type of CTE. For the class of 1992, technology coursework had a significant positive effect on the likelihood of being employed, while trade coursework had a significant negative effect. For the class of 2004, health coursework had a significant negative effect on employment for high school graduates who pursued no further education. There are notable differences between the effects of CTE coursework on employment for all high school graduates in table 7 and those high school graduates who pursued no further education in table 8 . For the class of 1982, technology had significant positive effects for the complete cohort, but these effects were smaller and no longer significant for those who did not pursue post-secondary education. For the 1992 cohort, trade coursework had more negative effects on employment for the less educated, and technology had much more positive effects for those with only a high school diploma. For graduates from the class of 2004, the coefficients increased in the areas of general CTE and home economics for high school graduates who pursued no further education, but became insignificant because of the much smaller $N$ for the sub-sample in table 8.

Table 9 measures the impact of varying amounts and types of CTE completion on employment for high school graduates with some post-secondary experience or an associate's degree completed. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes specific types of CTE courses to predict employment. This table shows few effects for participants who completed some college on employment. However, for the class of 2004, agriculture coursework had a significant positive effect on employment.

Table 10 measures the impact of varying amounts and types of CTE completion on employment for participants who completed a bachelor's degree or higher. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes specific types of CTE courses to predict employment. For the class of 1982, health had significant positive effects on employment for the more educated members of the cohort, interestingly; health coursework did not have significant positive effects on employment for less educated members of this cohort. For the class of 1992, technology, and business and marketing coursework had significant positive effects on the likelihood of being employed. For the class of 2004, there was no significant effect of any type of CTE. Across tables 6 through 10 the negative effects on educational attainment after high school graduation seem much stronger than the effects on employment.

## Effects of Career and Technical Education on Earnings

Table 11 presents OLS regression models measuring the effect of varying amounts and types of CTE on (inflation adjusted) earnings. The first equation uses background characteristics to predict annual income. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes specific types of CTE courses to predict earnings, while the fourth model gives the direct effect of CTE on earnings and also shows the extent to which CTE mediates the effects of varying levels of post-secondary degree attainment. The percent of vocational coursework completed as a part of total high school coursework has significant
negative consequences for graduates from the classes of 1982 and 1992. In the 2004 cohort, there was an insignificant positive effect of the percent of CTE completed in high school on earnings; it appears that the control variables matter more in this most recent cohort. The completion of agriculture coursework has positive, but insignificant implications on earnings for the classes of 1992 and 2004. Completing health coursework has insignificant negative implications that become positive, but also insignificant in later cohorts. Home economics and consumer home economics have negative and significant impacts on earnings across all three cohorts. Unsurprisingly, both the completion of Bachelor's and Master's degrees has positive and significant earnings implications.

Tables 12, 13 and 14 are similar to table 11 in that they analyze the effect of completing varying amounts and types of CTE in high school. The difference is that participants are split based on their highest level of education completed at the final data collection for their respective cohort. The first equation uses background characteristics to predict annual income. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes specific types of CTE courses to predict earnings. For high school graduates with no additional education, general CTE has negative and significant consequences for members of the graduating classes of 1992 and 2004. For high school graduates who completed no additional schooling, the percent of high school coursework that was CTE had negative but insignificant effects for all cohorts on earnings. For those who completed some college, percent CTE coursework had an insignificant negative effect on the class of 1982 that became positive in 1992 and became even more positive in 2004, nearing significance. High school graduates who completed an Associate's degree or some college had positive earnings outcomes for completing
trade coursework as high school students. This was positive and significant for the 2004 graduates who completed trade coursework. Home economics and consumer home economics have negative and significant impacts on earnings across all three cohorts for participants who completed some college, and those who completed bachelor's degrees or higher. For participants who completed a bachelor's degree or higher, the percent of vocational coursework completed as a part of total high school coursework has negative consequences for all cohorts, and is significant for high school graduates from 1982 and 1992.

## Career and Technical Course Completion Effect on Earnings for Females and Males

Figure 4 shows the distribution of earnings by number of vocational courses completed for each cohort of female and male high school graduates. These earnings are inflation adjusted to 2013 dollars using calculations from the Bureau of Labor Statistics. Across all three cohorts, graduates who completed fewer CTE courses earned more ten (HS\&B) and eight years (NELS \& ELS) after high school graduation. The difference between earnings for males within the same cohort was relatively small in the 1982 and 2004 cohorts, but was much larger for the 1992 cohort. The 2004 cohort earned less than their predecessors in the 1992 cohort; much of this is driven by females, of whom only $64 \%$ were working full-time and $26 \%$ were enrolled in postsecondary education. This reduction in employment and increase in schooling at the time of the 4th follow-up explains some of the drop in earnings from 1992 and 2004. Overall, it appears that the more CTE courses completed in high school, the smaller the earnings are for both female and male high school graduates.

Figure 4
Mean Earnings of by CTE Course Completion and Sex

## Effects of Career and Technical Course Completion on Post-Secondary Education for

## Females and Males

Table 15 presents odds ratio coefficients from multinomial logistic models measuring the effect of varying amounts and types of CTE on post-secondary educational attainment for females and males. The first equation uses background characteristics to predict educational attainment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model includes interactions between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict postsecondary attainment. Across all three cohorts males were less likely to complete higher levels of education in all of the first models with background characteristics. In the more complex model that included the interaction terms, the percent of vocational coursework completed had significant negative effects, while being male no longer had significant negative effects. In the

1982 cohort the interaction between percent vocational coursework and male had strong positive effects on participating in some college or completing a bachelor's degree.

## Effects of Career and Technical Course Completion on Employment for Females and Males

Table 16 presents odds ratio coefficients from logistic regressions estimating the impact of varying amounts and types of CTE completion on the likelihood of having any type of employment nine (HS\&B) and seven (ELS \& NELS) years after high school graduation. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict employment. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict employment. SES is a stronger predictor of employment for the class of 2004 than the classes of 1992 or 1982. Across all three cohorts, being male was one of the strongest predictors of employment even in the most complex models. For the class of 1982, in the third model, the interaction between male and percent vocational has significant positive effects on employment. For the same cohort in the fourth model, technology coursework has significant positive effects on employment. And finally, in the fifth model, home economics/consumer home economics coursework had significant negative impacts on employment, while the interaction between being male and home economics/consumer home economics coursework had significant positive impacts on employment. This indicates that home
economics/consumer home economics coursework hurt females' chances of employment and helped males. Similar to the earlier cohort, for the class of 1992, in the third model, the interaction between male and percent vocational has significant positive effects on employment. In the fifth model with interactions, technology, the interaction between being male and completing military coursework and the interaction between being male and completing home economics/consumer home economics coursework all had significant positive effects on employment. For the class of 2004, in the fourth model, agriculture and home economics/consumer home economics coursework had significant negative effects on employment. In the fifth model, with interactions, home economics/consumer home economics continued to have a significant negative effect, while the interaction between being male and completing agriculture coursework had a significant positive effect on employment.

Table 17 presents odds ratio coefficients from logistic regressions estimating the impact of varying amounts and types of CTE completion on employment for one of the most vulnerable populations in the economy, high school graduates with no post-secondary coursework completed for females and males. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict employment. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict employment. Similarly to the complete sample in table 3, across all three cohorts of high school graduates with no post-secondary education in table 4, being male was one of the strongest predictors of
employment even in the most complex models. For the class of 1982, the interaction between being male and completing home economics/consumer home economics had significant positive effects on employment. For 1992 graduates, in model 3 the interaction between the total number of high school units completed and being male had a significant negative effect on employment. In model 4, completing trade coursework had significant negative effects on employment, while in both models 4 and 5 technology coursework had significant positive effects on employment for participants who finished their education with a high school diploma. For the class of 2004, in both models 4 and 5 health courses significantly decreased the likelihood of employment, while in model 5 , the interaction between being male and military coursework significantly increased the likelihood of employment.

Table 18 presents odds ratio coefficients from logistic regressions estimating the impact of varying amounts and types of CTE completion on employment for high school graduates with some post-secondary experience or an associate's degree completed for females and males. Similarly to the models in previous tables, in the first equation of table 18 , I use background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict employment. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict employment. For graduates from the class of 1982 who completed some college, in model 5 with interactions, agriculture coursework significantly decreased the likelihood of employment while the interaction between being male and completing agriculture coursework significantly
increased the likelihood of employment. This finding indicates that agriculture coursework hurt females' chances of employment while helping males. For the class of 1992, in model 5 with interactions, military coursework significantly decreased the likelihood of employment while the interaction between being male and completing military coursework significantly increased the likelihood of employment. This finding indicates that military coursework hurt female's chances of employment while helping males. For the class of 2004, in model 4 completing agriculture coursework significantly increased the likelihood of employment, while in model 5 home economics/consumer home economics coursework had significant negative effects on employment.

Table 19 presents odds ratio coefficients from logistic regressions estimating the impact of varying amounts and types of CTE completion on employment for participants who completed a bachelor's degree or higher for females and males. The first equation uses background characteristics to predict employment. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict employment. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict employment. For the class of 1982, completing health coursework significantly increased the likelihood of employment in both models 4 and 5 for participants who completed a bachelor's degree or higher. In the fifth model, military coursework significantly decreased the likelihood of employment while the interaction between being male and completing military coursework significantly increased the likelihood of employment. This finding indicates that
military coursework hurt females' chances of employment while helping males. For the class of 1992, in model 4, completing technology and business coursework increased the likelihood of employment. In model 5, health coursework decreased the likelihood of employment, while the interaction of being male and completing health coursework did not have any effect on employment. For the class of 2004 who completed a bachelor's degree or higher, only the interaction between being male and completing agriculture coursework significantly increased the likelihood of employment.

## Effects of Career and Technical Course Completion Earnings for Females and Males

Table 20 is a regression model measuring the effect of varying amounts and types of CTE on earnings for females and males. The first equation uses background characteristics to predict earnings. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict earnings. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict earnings. Across all cohorts and models, being male, and of higher SES during high school had significant positive effects on earnings. For graduates from both 1982 and 1992, the percent of vocational coursework completed had significant negative effects on earnings. Additionally across all cohorts, in model 4 with coursework and model 5 with coursework interacted with being male, completing home economics/consumer home economics coursework had significant negative effects on earnings.

Tables 21, 22 and 23 are similar to table 20 in that they analyze the effect of completing varying amounts and types of CTE in high school. The difference is that participants are split based on their highest level of education completed at the final data collection for their respective cohort. The first equation uses background characteristics to predict earnings. The second equation adds total high school units and a continuous variable measuring the percent of CTE units out of the total number of high school units completed. The third model adds interaction terms between being male and both total high school units and the percent of CTE units out of the total number of high school units completed to predict earnings. The fourth model includes specific types of CTE courses, and the fifth model includes interactions between males and the specific CTE course types to predict earnings. For high school graduates who completed their education with a high school diploma in 2004, model 4 shows that technology coursework had significant negative effects on earnings. For participants with some college completed, across the cohorts home economics/consumer home economics coursework negatively impacted earnings in model 4 . The negative effect increased when controlling for the interaction between being male and completing home economics/consumer home economics coursework. In the earliest cohort the earnings effects were significant, but the effects decreased over time. For graduates from the class of 2004 who completed some college, the percent of vocational coursework completed had significant positive effects on earnings, as did trade, which was largely driven by males. In table 10 , for college graduates who completed high school in 1982 and 1992, home economics/consumer home economics coursework negatively impacted earnings in model 4. The negative effect increased when controlling for the interaction between being male and completing home economics/consumer home economics coursework in model 5 .

For the 1982 and 1992 high school graduates, the percent vocational coursework completed had significant negative effects on earnings.

## Chapter 5: Discussion and Conclusion

## Changes in Career and Technical Course Completion Over Time

Over time, high school graduates from the graduating classes of 1982, 1992 and 2004 took fewer overall units in CTE. A decrease in general CTE units completed occurred between 1982 and 1992 and persisted in 2004. An increase in technical CTE units completed occurred between 1982 and 1992 and persisted in 2004. Technology course completion increased significantly from the class of 1982 to the 1992 cohort and remained high in 2004. Additionally, there was a small, but increasing group of high school graduates that completed health coursework. A more mixed academic and vocational high school experience was observed; this finding is consistent with prior research on tracking and CTE (Lucas, 1999; Neumark, 2007).

## Differences in Career and Technical Course Completion for Females and Males

Across the three decades there have been notable differences in the types of CTE courses male and female high school graduates completed. The overall drop in total CTE units from the 1992 to 2004 cohorts was largely driven by a decrease in CTE units completed by females. Additionally, across all three cohorts male high school graduates completed more trade coursework than their female counterparts. Additionally, females completed far more business and marketing coursework in 1982 than males, but that difference decreased in 1992 and females and males completed nearly the same amount of business and marketing units in 2004. The average number of units of health coursework completed increased across the three cohorts; although both male and females completed more health courses over time, the largest increase in health units occurred for males.

## Post-Secondary Attainment and Earnings

I hypothesized that all types of high school CTE would have negative effects on postsecondary degree attainment across cohorts. This hypothesis is based on previous work identifying large negative effects of high school CTE on post-secondary enrollment (Ainsworth \& Roscigno, 2005; Arum, 1998; Arum \& Shavit, 1995). Table 6 shows similar findings to prior research, showing that increasing the percent of vocational coursework completed as a part of total high school coursework decreases the likelihood of completing any type of post-secondary education across all cohorts. The completion of the majority of CTE course types decreased the likelihood of completing future education. This was true for all but health and technology coursework, consistently did not have adverse implications for completing further education beyond high school across all three cohorts, the one exception is the effect health on the attainment of a Master's degree or higher in the 1992 cohort.

These findings about educational attainment differ from Bozick and Dalton's research, which used an earlier wave of data from ELS: 2002 and determined that most of the school achievement differences between students who take a large number of occupational courses and students who take few or no occupational courses are largely due to preexisting differences between students before they enter high school, not the actual courses completed. Their work focuses on what occurs during high school, while mine focuses on the consequences of high school behaviors on future outcomes. In my work, I find that even with controls similar to what Bozick and Dalton used, such as total credits and vocational credits, CTE had significant negative effects on post-secondary degree attainment as measured in follow-up four of ELS.

Previous research on employment found that vocational education may inhibit future educational and occupational plans for some students, however, others argue that vocational
education teaches students marketable skills and attitudes that can help them find skilled jobs and reduce their risk of unemployment or employment as low paid, un-skilled workers (Arum \& Shavit, 1995). Table 8 measures the likelihood of being employed for high school graduates who pursued no further education. This group is arguably the least-skilled and therefore the most vulnerable population in the labor market. For the class of 1982 there was no significant effect of any type of CTE. For the class of 1992, only technology coursework had a significant positive effect on the likelihood of being employed, while trade coursework had a significant negative effect. For the class of 2004, health coursework had a significant negative effect on employment. These findings do not demonstrate strong support of previous findings in increasing employability, however this finding is consistent with the literature on the recession that health care jobs increased while many other sectors faltered.

The results from this study are consistent with prior research showing large negative effects of high school CTE on all types of post-secondary enrollment. With negative implications on further education beyond high school, one must examine the impact on employment and earnings. If the current educational agenda in high schools is to graduate "college and career ready" (United States Department of Education, 2010) students, then efforts must be made to ensure that students are prepared with coursework that equips them for decent employment where they can earn a living wage or for post-secondary education. However, most CTE coursework across cohorts had little effect on employment; this is despite the potential selection bias inherent in CTE courses that often attracts lower performing students. Surprisingly, despite the efforts to increase employability, for the class of 2004, the percent of vocational coursework completed in high school, general CTE and home economics/consumer home economics had significant negative consequences on employment.

In conjunction with employment, earnings must also be considered when evaluating the effect of CTE coursework. I hypothesized that the impact of high school vocational education would have negative implications across cohorts on earnings. This hypothesis is based on findings that the impact of high school vocational education, finding little long-term economic benefit (Gustman \& Steinmeier, 1983; Meyer \& Wise, 1979; Neuman \& Ziderman, 1999). However, I found mixed effects of CTE on earnings based on the type of CTE completed in high school. Completing health coursework has insignificant negative implications that become positive, but also insignificant in later cohorts. This is noteworthy given the decrease in overall earnings in the first decade of the 2000s when ELS labor-market outcomes were collected. Once again, home economics and consumer home economics have negative and significant impacts on earnings. Despite a reduction in both the number of participants completing home economics and consumer home economics as well as the mean number of units completed, this type of CTE coursework persists in its significant negative impact on earnings as shown in table 11. Surprisingly, despite concentrated job losses in goods-producing industries of manufacturing and construction (Sahin, Song \& Hobijn, 2010), my analysis shows a significant positive effect of Trade coursework on earnings. It is possible that more trained workers in this field were less likely to lose their jobs.

## The Effect of Career and Technical Course Completion for Females and Males

In prior research on the effect of CTE course completion in high school on postsecondary attainment, Arum and Shavit (1995) found that regardless of gender, CTE had negative effects on post-secondary enrollment. In this study I found that increasing the percent of
vocational coursework completed during high school had significant negative effects on all education beyond high school for both males and females.

My final hypothesis was that males who complete CTE coursework in high school earn more than their female counterparts because they are completing preparation for higher wage occupations. This is based on the findings about gender roles in labor market preparation from the National Center for Education Statistics, 1991; National Women's Law Center, 2005; and Sadker \& Zittleman, 2009. In prior research, differences in CTE training by gender result in distinctly different employment opportunities with male dominated CTE fields paying an average wage of $\$ 19.62$, while female fields pay $\$ 15.32$ per hour (National Women's Law Center, 2009). Correspondingly, completing home economics/consumer home economics significantly decreased the likelihood of being employed.

In this study, I also found that across the three decades, many more females completed home economics coursework than males. In all three decades this coursework negatively impacted earnings. Additionally, the negative effect increased when controlling for the interaction between being male and completing home economics/consumer home economics coursework. If participants in home economics/consumer home economics coursework are less likely to be employed, and earn less, what purpose does this coursework serve in the labor market? Prior research has shown that in fact, students trained in female dominated career and technical courses like home economics/consumer home economics are at a large wage disadvantage when compared to those who enroll in a male dominated CTE (National Women's Law Center, 2009). This is in contrast to the current outcomes for those students who complete home economics/consumer home economics and are likely to encounter poverty and limited future educational opportunities. Therefore, policy makers should consider what purpose home
economics/consumer home economics courses serve to the future academic trajectory, especially for females who are less likely to work full-time and earn lower wages than their male counterparts.

For males in the most recent cohort, analyses show that interactions between high school CTE trade, business and marketing and being male had positive significant effects on wages in 2011 even when controlling for family SES and prior achievement. With young men enrolling and completing college at lower rates and facing higher unemployment rates than their female counterparts at this time, these high school CTE courses provide a pathway to employment even when the economy was faltering. This finding that CTE training mediated some of the negative effects of a downturn in the economy for young men should be investigated further in future research to examine specifically which sub-groups of young men benefited most from CTE in high school.

## Limitations and Future Research

This analysis is limited to students with complete transcript data from on-time high school graduates, which includes $80 \%$ of survey participants across the three cohorts and disproportionately excludes high school dropouts. Therefore, these conclusions have limited generalizability beyond high school graduates. Additionally, descriptive statistics suggest that the subsample of participants analyzed in this study is slightly more White, Asian and female, and less Black, Hispanic and male than the complete samples of HS\&B, NELS and ELS. In HS\&B $76 \%$ of all graduates completed some general CTE, which is much higher than the $21 \%$ and $37 \%$ of graduates from NELS and ELS respectively. This could be the result of less sophisticated course documentation in 1982 and may not reflect the true variation in courses completed by the
earliest cohort in the study. Selection bias in the type of students that high school CTE classes attract likely impacts all outcomes; controls have been used, but it is possible that additional controls could be added to the models to decrease omitted variable bias.

Note. Full-time employment for on-time high school graduates who are not currently enrolled in post-secondary education

[^0]:    ${ }^{1}$ corestandards.org

[^1]:    ${ }^{2}$ Using the CSSC course level coding, I applied the year 2000 definitions of vocational courses to all three cohorts in order to use a single set of definitions of vocational specializations (Badby \& Hudson, 2007). In the 2000 CSSC there were 22 vocational concentrations including: engineering technologies, computer science, marketing, business, construction and agriculture.

[^2]:    ${ }^{3}$ This is also one definition of a "New Basics" curriculum.

[^3]:    ${ }^{4}$ http://www.bls.gov/data/inflation_calculator.htm

[^4]:    ${ }^{5}$ CTE specializations and the courses from CSSC that fulfill each specialization are found in table 4 in the appendix.
