## EVIDENCE OF ASSOCIATIONS BETWEEN <br> NEUROTRANSMITTER CANDIDATE GENES AND PERSISTENT ARM PAIN SEVERITY FOLLOWING BREAST <br> CANCER SURGERY

by
Jessica Michelle Storlie

THESIS

Submitted in partial satisfaction of the requirements for the degree of
MASTER OF SCIENCE
in
Nursing
in the

GRADUATE DIVISION
of the

UNIVERSITY OF CALIFORNIA, SAN FRANCISCO

## ACKNOWLEDGMENTS

I would like to express my special appreciation and thanks to my advisors Dr. Christine Miaskowski and Dr. Bradley Aouizerat for their guidance and support. I would also like to thank my committee members, Dr. Heather Leutwyler and Dr. Laura Dunn. In addition, thank you to the American Cancer Society for their financial support, granted through the Graduate Scholarship in Cancer Nursing Practice.

# EVIDENCE OF ASSOCIATIONS BETWEEN NEUROTRANSMITTER CANDIDATE GENES AND PERSISTENT ARM PAIN SEVERITY FOLLOWING BREAST CANCER SURGERY Jessica Storlie 

#### Abstract

Persistent arm pain, a distinct syndrome from persistent breast pain, is a considerable clinical problem following breast cancer surgery. The roles of neurotransmitters and neurotransmitter genes have been examined in persistent neuropathic pain; however, genetic associations have not been examined in the setting of breast cancer surgery. In this study, associations between previously identified arm pain classes (i.e., No Arm Pain vs. Mild Arm Pain and No Arm Pain vs. Moderate Arm Pain) and single nucleotide polymorphisms (SNPs) over 30 candidate neurotransmitter genes were evaluated. After multivariate logistic regression analyses for phenotypic characteristics, 4 SNPs and 1 haplotype remained significant between the No Arm Pain and Mild Arm Pain classes: 1 SNP in BDNF (i.e., rs11030102), 1 SNP in COMT (i.e., rs4633), 1 haplotype in HTR2A (i.e., Haplotype B02), 1 SNP for HTR3A (i.e., rs1985242), and 1 SNP in TH (i.e., rs2070762). Between the No Arm Pain and Moderate Arm Pain classes, 9 SNPs remained significant: 1 SNP in BDNF (i.e., rs2049046), 1 SNP in COMT (i.e., rs165656), 2 SNPs in HTR2A (i.e., rs2770298 and rs9534511), 1 SNP in HTR3A (i.e., rs1985242), 1 SNP in NOS2A (i.e., rs2248814), 1 SNP in NPY (i.e., rs16148), 1 SNP in SLC6A1 (i.e., rs2601126), and 1 SNP in TACR1 (i.e., rs4439987). These findings suggest meaningful impact of neurotransmitter genes on the development of persistent arm pain following breast cancer surgery.

## INTRODUCTION

Surgery is the primary treatment for breast cancer. Following surgery, between $25 \%$ and $60 \%$ of patients report chronic, persistent pain. ${ }^{1}$ This persistent pain syndrome is characterized by burning, throbbing, or aching in the ipsilateral chest, axilla, and/or arm. The syndrome is associated with other breast and arm symptoms, such as swelling and weakness. In a review of 60 studies, ${ }^{1}$ Andersen and Kehlet examined preoperative, intraoperative, and postoperative factors associated with persistent pain after breast cancer surgery. While this review identified several demographic and clinical characteristics associated with the development of persistent pain, the authors did not distinguish between persistent breast and persistent arm pain. Only 13 studies were found that focused on the occurrence and predictors of persistent arm pain. In one study that segregated breast and ipsilateral arm pain, ${ }^{2} 17 \%$ of patients reported persistent ipsilateral arm pain one year after surgery.

In a study conducted by our research team, patients ( $\mathrm{n}=398$ ) were evaluated prior to and for six months following breast cancer surgery. Separate phenotypic characterizations of persistent breast ${ }^{3}$ and arm ${ }^{4}$ pain were reported previously. In terms of persistent arm pain, four distinct persistent Arm Pain groups were identified. Patients in the No Arm Pain group (41.6\%) did not report any arm/shoulder pain over the six months of the study. However, using growth mixture modeling (GMM), two distinct subgroups were identified (i.e. Mild Arm Pain (23.67\%) and Moderate Arm Pain (34.8\%)). When the persistent breast and arm pain classes were compared, ${ }^{3,4}$ distinct demographics and clinical characteristics differentiated between the two anatomic sites. These findings suggest that persistent arm/shoulder pain represents a different pain condition from persistent breast pain.

A variety of neurotransmitters modulate pain transmission in the peripheral and central nervous systems. ${ }^{5-8}$ A number of recent reviews have summarized the preclinical ${ }^{9,10}$ and clinical ${ }^{9,11,12}$ studies that have evaluated associations between polymorphisms in a number of
neurotransmitter genes and a variety of neuropathic pain conditions. Some of the most widely investigated neurotransmitter genes, that appear to play a role in the modulation of persistent pain, include catechol-O-methyltransferase (COMT) and the 5-hydroxytryptamine receptor (HTR) genes. To date, no studies were identified that evaluated the role of neurotransmitter genes in patients with persistent arm pain following breast cancer surgery. Therefore, building on our work that identified two persistent arm pain groups, ${ }^{4}$ the purposes of this study in a sample of women ( $n=398$ ) who were evaluated prior to and for six months after breast cancer surgery were to evaluate for associations between polymorphisms in a number of neurotransmitter genes and membership in the Mild Arm Pain class compared to the No Arm Pain class, as well as membership in the Moderate Arm Pain class compared to the No Arm Pain class.

## MATERIALS AND METHODS

This study is part of a larger, longitudinal study that evaluated for neuropathic pain and lymphedema in a sample of women who underwent breast cancer surgery. The methods used in this study are described in detail elsewhere. ${ }^{13,14}$

## Patients and Settings

In brief, patients were recruited from Breast Care Centers located in a Comprehensive Cancer Center, two public hospitals, and four community practices. Patients were eligible to participate if they: were an adult woman ( $\geq 18$ years) who would undergo breast cancer surgery on one breast; were able to read, write, and understand English; agreed to participate; and gave written informed consent. Patients were excluded if they were having breast cancer surgery on both breasts and/or had distant metastasis at the time of diagnosis. A total of 516 patients were approached to participate and 410 were enrolled in the study (response rate $79.5 \%$ ). The major reasons for refusal were: too busy, overwhelmed with the cancer diagnosis, or insufficient time available to do the assessment prior to surgery.

## Instruments

The demographic questionnaire obtained information on age, education, ethnicity, marital status, employment status, living situation, and financial status. The Karnofsky Performance Status (KPS) scale is widely used to evaluate functional status in patients with cancer and has well established validity and reliability. ${ }^{15,16}$ Patients rated their functional status using the KPS scale that ranged from 30 (I feel severely disabled and need to be hospitalized) to 100 (I feel normal; I have no complaints or symptoms). Patients were asked to indicate if they exercised on a regular basis (yes/no format).

The Self-Administered Comorbidity Questionnaire (SCQ) is a short and easily understood instrument that was developed to measure comorbidity in clinical and health service research settings. ${ }^{17}$ The questionnaire consists of 13 common medical conditions that were
simplified into language that could be understood without any prior medical knowledge. Patients were asked to indicate if they had the condition; if they received treatment for it; and did it limit their activities. For each condition, a patient can receive a maximum of 3 points. The SCQ has well-established validity and reliability and was used in studies of patients with a variety of chronic conditions. ${ }^{17-21}$

Persistent and postsurgical pain were evaluated using the Arm/Shoulder Symptoms Questionnaire (ASQ) and Postsurgical Pain Questionnaire. The ASQ is an adaptation of the Brief Pain Inventory (BPI). ${ }^{22}$ The ASQ consisted of two parts. Part 1 obtained information on the occurrence of pain in the arm and shoulder area. If the patient had pain in the shoulder, arm, or hand, they completed Part 2 of the ASQ. Patients were asked to rate the intensity of their average and worst pain using a numeric rating scale (NRS) that ranged from 0 (no pain) to 10 (worst imaginable pain). ${ }^{23}$

The Postsurgical Pain Questionnaire evaluated pain intensity in the first 24 to 48 hours after surgery. Average and worst pain were rated using a 0 (no pain) to 10 (worst imaginable pain) NRS. This questionnaire was completed during the month 1 study visit.

## Study Procedures

The study was approved by the Committee on Human Research at the University of California, San Francisco and by the Institutional Review Boards at each of the study sites. During the patient's preoperative visit, a clinician explained the study to the patient and determined her willingness to participate. For those women who were willing to participate, the clinician introduced the patient to the research nurse. The research nurse met with the women, determined eligibility, and obtained written informed consent prior to surgery. After obtaining written informed consent, patients completed the enrollment questionnaires (Assessment 0).

Patients were contacted two weeks after surgery to schedule the first postsurgical appointment. The research nurse met with the patients either in their home or in the Clinical Research Center at 1, 2, 3, 4, 5, and 6 months after surgery. During each of the study visits, the
women completed the study questionnaires and provided information on new and ongoing treatments. Over the course of the study, patients' medical records were reviewed for disease and treatment information.

## Characterization of the persistent arm pain phenotype

Characterization of the persistent arm pain phenotype used in this study was described previously. ${ }^{4}$ Data were analyzed using SPSS Version $22^{24}$ and Mplus Version 6.1. ${ }^{25}$ Demographic and clinical characteristics and symptom severity scores were analyzed using descriptive statistics and frequency distributions.

Unconditional GMM with robust maximum likelihood estimation was carried out to identify latent classes of patients with distinct persistent arm pain trajectories. Arm/shoulder pain scores were assessed monthly for 6 months following breast cancer surgery. Prior to conducting the GMM analysis, patients who reported no pain in their affected arm/shoulder for all 6 assessments were identified ( $\mathrm{n}=164,41.6 \%$ ) and not included in the GMM analysis. The remaining 230 women's ratings of worst arm/shoulder pain were used in the GMM analysis. These methods are described in detail elsewhere. ${ }^{26}$ In brief, a single growth curve that represented the "average" change trajectory was estimated for the sample. Then, the number of latent growth classes that best fit the data was identified using guidelines recommended in the literature. ${ }^{27-29}$

Descriptive statistics and frequency distributions for the No Arm pain, Mild Arm Pain, and Moderate Arm Pain classes were generated for demographic and clinical characteristics using SPSS version 22 and Stata version 13 (StataCorp, College Station, TX). Independent sample ttests, Mann-Whitney U tests, Chi square tests, and Fisher's Exact tests were used to evaluate for differences in demographic and clinical characteristics between the No Arm Pain and the Mild Arm Pain and between the No Arm Pain and the Moderate Arm Pain classes. Logistic regression analyses were performed to evaluate the association between phenotypic characteristics and pain group membership. All phenotypic characteristics that were identified in
the bivariate analyses as being different between the No Arm Pain and each of the two persistent arm pain classes were evaluated for inclusion in the multivariate analysis. A backwards stepwise approach was used to create a parsimonious model. Only predictors with a p -value of <. 05 were retained in the final model. These predictors were used in each of the logistic regression analyses to evaluate the associations between genotype and pain group membership.

## Gene Selection

A total of 30 candidate genes involved in various aspects of neurotransmission, drug metabolism, or transport of molecules across cell membranes were evaluated. Genes involved in catecholaminergic neurotransmission included adrenergic, alpha-1D receptor (ADRA1D); adrenergic alpha-2A receptor (ADRA2A); adrenergic beta-2 receptor (ADRB2); adrenergic, beta-3 receptor (ADRB3); adrenergic, beta, receptor kinase 2 (ADRBK2); COMT; solute-like carrier (SLC) family 6 (neurotransmitter transporter, noradrenaline) member 2 (SLC6A2); and SLC family 6 (neurotransmitter transporter, dopamine) member 3 (SLC6A3). The gene involved in the GABAergic system was SLC family 6 (neurotransmitter transporter, GABA) member 1 (SLC6A1). Genes involved in serotonergic neurotransmission included: GTP cyclohydrolase 1 (GCH1); HTR 1A, G protein coupled (HTR1A); HTR 1B, G protein coupled (HTR1B); HTR 2A, G protein coupled (HTR2A); HTR 3A, G protein coupled (HTR3A); SLC family 6 (neurotransmitter transporter, serotonin) member 4 (SLC6A4); tyrosine hydroxylase (TH); and tryptophan hydroxylase 2 (TPH2). The two genes involved in molecular transport and drug metabolism that were evaluated were: ATP-binding cassette, subfamily B (MDR/TAP) member 1 (ABCB1) and cytochrome P450, family 3, subfamily A, polypeptide 4 (CYP3A4). A number of additional genes that are involved in various aspects of neurotransmission that were evaluated included: brainderived neurotrophic factor (BDNF); galanin (GAL); galanin receptor 1 (GALR1); galanin receptor 2 (GALR2); nitric oxide synthase 1 (NOS1); nitric oxide synthase 2, inducible (NOS2A);
neuropeptide Y (NPY); neuropeptide Y receptor Y 1 (NPYR1); prodynorphin (PDYN); tachykinin, precursor 1 (TAC1); and tachykinin receptor 1 (TACR1).

Blood collection and genotype
Genomic deoxyribonucleic acid (DNA) was extracted from peripheral blood mononuclear cells using the PUREGene DNA Isolation System (Invitrogen, Carlsbad, CA). DNA samples were quantitated with a Nanodrop Spectrophotometer (ND-1000; Nanodrop Products, Wilmington, DE) and normalized to a concentration of $50 \mathrm{ng} / \mu \mathrm{L}$ (diluted in 10 mM Tris $/ 1 \mathrm{mM}$ EDTA). Samples were genotyped using the Golden Gate genotyping platform (Illumina, San Diego, CA) and processed using GenomeStudio (Illumina, San Diego, CA). Two blinded reviewers visually inspected signal intensity profiles and resulting genotype calls for each single nucleotide polymorphism (SNP).

## SNP selection

A combination of tagging SNPs and literature driven SNPs were selected for analysis. Tagging SNPs were required to be common (i.e., defined as having a minor allele frequency (MAF) of $\geq .05$ ) in public databases. In order to ensure robust genetic association analyses, quality control filtering of SNPs was performed. SNPs with call rates $<95 \%$, Hardy-Weinberg p <.001, and/or a MAF of $<5 \%$ were excluded. As shown in Table 1, a total of 249 SNPs among the 30 candidate genes passed all quality control filters and are included in subsequent analyses. Potential functional roles of SNPs associated with persistent arm pain were examined using PUPASuite 2.0. ${ }^{30}$

## Statistical analyses

Allele and genotype frequencies were determined by gene counting. Hardy-Weinberg equilibrium was assessed by the Chi-square test. Measures of linkage disequilibrium (i.e., D' and $r^{2}$ ) were computed with Haploview 4.2. Linkage disequilibrium (LD)-based haplotype block definition was based on the $D^{\prime}$ confidence interval method. ${ }^{31}$

For SNPs that were members of the same haploblock, haplotype analyses were conducted in order to localize the association signal within each gene and to determine if haplotypes improved the strength of the association with the phenotype. Haplotypes were constructed using the program PHASE version 2.1. ${ }^{32}$ In order to improve the stability of haplotype inference, the haplotype construction procedure was repeated five times using different seed numbers with each cycle. Only haplotypes that were inferred with probability estimates of $\geq .85$, across the five iterations, were retained for downstream analyses.

Ancestry informative markers (AIMs) were used to minimize confounding due to population stratification. ${ }^{33-35}$ Homogeneity in ancestry among patients was verified by principal component analysis ${ }^{36}$ using Helix Tree (Golden Helix, Bozeman, MT). Briefly, the number of principal components (PCs) was sought which distinguished the major racial/ethnic groups in the sample by visual inspection of scatter plots of orthogonal PCs (i.e., PC 1 versus PC2, PC2 versus PC3). The first three PCs were selected to adjust for potential confounding due to population substructure (i.e., race/ethnicity) by including the three covariates in all regression models. One hundred and six AIMs were included in the analysis.

For association tests, three genetic models were assessed for each SNP: additive, dominant, and recessive. Barring trivial improvements (i.e., delta $<10 \%$ ), the genetic model that best fit the data, by maximizing the significance of the p-value, was selected for each SNP. Logistic regression analysis, that controlled for significant covariates, as well as genomic estimates of and self-reported race/ethnicity, was used to evaluate the associations between genotype and pain group membership. A backwards stepwise approach was used to create a parsimonious model. Except for genomic estimates of and self-reported race/ethnicity, only predictors with a p-value of $<.05$ were retained in the final model. Genetic model fit and both unadjusted and covariate-adjusted odds ratios were estimated using Stata version 13.0.

As was done in our previous studies, ${ }^{14,37}$ based on recommendations in the literature, ${ }^{38,39}$ as well as the implementation of rigorous quality controls for genomic data, the non-
independence of SNPs/haplotypes in LD, and the exploratory nature of the analyses, adjustments were not made for multiple testing. Significant SNPs identified in the bivariate analyses were evaluated further using regression analyses that controlled for differences in phenotypic characteristics, potential confounding due to population stratification, and variation in other SNPs/haplotypes within the same gene. Only those SNPs that remained significant are included in the final presentation of the results. Therefore, the significant independent associations reported are unlikely to be due solely to chance. Unadjusted associations are reported for all SNPs passing quality control criteria in Table 1 to allow for subsequent comparisons and meta-analyses.

RESULTS

## Differences in Demographic and Clinical Characteristics between No Arm Pain and Mild Arm

## Pain Classes

As summarized in Table 2, a number of significant differences in demographical clinical characteristics were found between the No Arm Pain and Mild Arm Pain classes. Patients in the Mild Arm Pain class were significantly younger, had more education, had a lower KPS score, and were less likely to have comorbid high blood pressure. In addition, women in the Mild Arm Pain class had a more advanced stage of disease, had a higher number of breast biopsies, had an axillary lymph node dissection, and had a greater number of nodes removed during surgery. A greater percentage of women in the Mild Arm Pain class had pain in the breast prior to surgery, reported strange sensations in the affected breast, and had increased severity in average and worst postoperative pain. Women in the Mild Arm Pain class were more likely to have had a surgical drain either in the breast, axilla, or both; had a higher number of drains; were more likely to have received neoadjuvant chemotherapy; and a higher percentage had received a biologic therapy during the six months following surgery.

Candidate gene analyses of for the No Arm Pain versus Mild Arm Pain Classes
As shown in Table 1, genotype distributions differed between the No Arm Pain and Mild Arm Pain classes for 4 SNPs and 1 haplotype in BDNF; 5 SNPs and 2 haplotypes in COMT; 1 SNP in GAL; 2 SNPs in GCH1; 3 SNPs and 1 haplotype in HTR2A; 2 SNPs and 1 haplotype in HTR3A; 2 SNPs and 1 haplotype in NOS1; 1 haplotype in NOS2A; 1 SNP in SLC6A2; and 1 SNP in TH.

Regression Analyses for BDNF, COMT, HTR2A, HTR3A, and TH Genotypes and No Arm Pain versus Mild Arm Pain Classes

In order to better estimate the magnitude (i.e. odds ratio, OR) and precision (95\% confidence interval, CI ) of genotype on the odds of belonging to the No Arm Pain as compared
to the Mild Arm Pain class, multivariate logistic regression models were fit. In these regression analyses that included genomic estimates of and self-reported race/ethnicity, the phenotypic characteristics that remained significant were: functional status (KPS score in 10 unit increments), pain in the affected breast prior to surgery, and undergoing an ALND.

Five genetic associations remained significant in the multivariate logistic regression analyses: BDNF rs11030102, COMT rs4633, HTR2A Haplotype B02, HTR3A rs1985242, and TH rs2070762 (Table 4). In the regression analysis for BDNF rs11030102, carrying one or two doses of the rare $G$ allele (i.e., CC versus CG+GG) was associated with a $64 \%$ decrease in the odds of belonging to the Mild Arm Pain class ( $\mathrm{p}=.008$ ). In the regression analysis for COMT rs4633, carrying two doses of the rare T allele (i.e., CC+CT versus TT) was associated with a $68 \%$ decrease in the odds of belonging to the Mild Arm Pain class ( $p=.012$ ). In the regression analysis for HTR2A Haplotype B02, that is composed of alleles at two SNPs (i.e., rs1923886 [common T allele], rs7330636 [rare T allele]), each additional dose of HTR2A HapB02 was associated with a $51 \%$ decrease in the odds of belonging to the Mild Arm Pain class ( $p=.008$ ). In the regression analysis for HTR3A rs1985242, carrying two doses of the rare A allele (i.e., TT+TA versus AA) was associated with a $90 \%$ decrease in the odds of belonging to the Mild Arm Pain class ( $\mathrm{p}<.001$ ).

## Differences in Demographic and Clinical Characteristics between No Arm Pain and Moderate

## Arm Pain Classes

As summarized in Table 3, a number of significant differences in demographic and clinical characteristics were found between the No Arm Pain and the Moderate Arm Pain classes. Patients in the Moderate Arm Pain class were younger, with lower KPS scores, lower annual household incomes, higher BMI, higher SCQ scores, and more likely to be White. In addition, a higher percentage of women in the Moderate Arm Pain class reported comorbid anemia and were less likely to have breast fed. A higher percentage of patients in the Moderate Arm Pain class had advanced stage of disease, reported breast pain prior to surgery, reported
sensations of swelling, numbness, and hardness in the affected breast, had received neoadjuvant chemotherapy, and had a higher number of breast biopsies. A higher percentage of women in the Moderate Arm Pain class underwent a mastectomy; had a higher number of lymph nodes removed; had a drain placed either in the breast, axilla, or both; had a higher number of drains placed; had an ALND; and had the intercostobrachial nerve sacrificed. Post operatively, women in the Moderate Arm Pain class reported higher average and worst postoperative pain severity scores; were more likely to have had physical therapy within the six months post-surgery; have received biological therapy within the six months following surgery; and had more postoperative complications.

## Candidate Gene Analyses for the No Arm Pain versus Moderate Arm Pain Classes

As shown in Table 1, genotype distributions differed between the No Arm Pain and Moderate Arm Pain classes for 1 SNP in ABCB1; 2 SNPs and 2 haplotypes in ADRA1D; 1 SNP in ADRBK2; 8 SNPs and 1 haplotype in BDNF; 5 SNPs and 4 haplotypes in COMT; 1 SNP in GALR2; 1 SNP in GCH1; 1 SNP in HTR1A; 7 SNPs and 3 haplotypes in HTR2A; 1 SNP and 1 haplotype in HTR3A; 2 SNPs and 1 haplotype in NOS2A; 1 SNP in NPY; 1 SNP in PDYN; 2 SNPs and 2 haplotypes in SLC6A1; 3 SNPs in SLC6A2; 1 SNP in SLC6A4; 7 SNPs in TACR1; and 1 SNP in TPH2.

Regression Analyses for BDNF, COMT, HTR2A, HTR3A, NOS2A, NPY, SLC6A1, and TACR1

## Genotypes and No Arm Pain versus Moderate Arm Pain classes

In order to better estimate the magnitude (i.e. odds ratio, OR) and precision (95\% confidence interval, CI ) of genotype on the odds of belonging to the No Arm Pain as compared to the Moderate Arm Pain class, multivariate logistic regression models were fit. In these regression analyses that included genomic estimates of and self-reported race/ethnicity, the phenotypic characteristics that remained significant were: functional status (KPS score in 10 unit increments), pain in the affected breast prior to surgery, number of breast biopsies in the past year, placement of a surgical drain (i.e., no drain placed compared to drain placement only in
the breast, drain placement only in the axilla, or drain placement in both the breast and axilla), and receipt of physical therapy in the six months following surgery.

Nine genetic associations remained significant in the multivariate logistic regression analyses: BDNF rs2049046, COMT rs165656, HTR2A rs2770298, HTR2A rs9534511, HTR3A rs1985242, NOS2A rs2248814, NPY rs16148, SLC6A1 rs2601126, and TACR1 rs4439987 (Table 5). In the regression analysis for BDNF rs2049046, carrying two doses of the rare T allele (i.e., $A A+A T$ versus TT) was associated with a 3.07 -fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.009$ ). In the regression analysis for COMT rs165656, carrying two doses of the rare G allele (i.e., CC+CG versus GG) was associated with a $63 \%$ decrease in the odds of belonging in the Moderate Arm Pain class ( $p=.027$ ).

For HTR2A, two SNPs were associated with membership in the Moderate Arm Pain class (i.e., HTR2A rs2770298, HTR2A rs9534511). In the regression analysis, for HTR2A rs2770298, carrying two doses of the rare C allele (i.e., TT+TC versus CC) was associated with a 5.08 -fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.028$ ). In the same regression analysis, for HTR2A rs9534511, carrying one or two doses of the rare T allele (CC versus CT+TT) was associated with a 1.89 -fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.019$ ). In the regression analysis for HTR3A rs1985242, carrying two doses of the rare A allele (i.e., TT+TA versus AA) was associated with an $85 \%$ decrease in the odds of belonging to the Moderate Arm Pain class ( $p=.003$ ).

In the regression analysis for NOS2A rs2248814, carrying one or two doses of the rare A allele (i.e., GG versus GA+AA) was associated with a $66 \%$ decrease in the odds of belonging to the Moderate Arm Pain class ( $p=.007$ ). In the regression analysis for NPY rs16148, carrying one or two doses of the rare C allele (i.e., TT versus $\mathrm{TC}+\mathrm{CC}$ ) was associated with a 2.70 -fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.021$ ). In the regression analysis of SLC6A1 rs2601126, carrying one or two doses of the rare T allele (i.e., CC versus $\mathrm{CT}+\mathrm{TT}$ ) was associated with a 3.00 -fold increase in the odds of belonging to the Moderate Arm

Pain class ( $p=.014$ ). In the regression analysis of TACR1 rs4439987, carrying one or two doses of the rare G allele (i.e., AA versus AG+GG) was associated with a $60 \%$ decrease in the odds of belonging to the Moderate Arm Pain class ( $p=.025$ ).

## DISCUSSION

## Phenotypic characteristics

A discussion of differences in phenotypic characteristics between the No Arm Pain and Mild Arm Pain classes, as well as between the No Arm Pain and Moderate Arm Pain classes are reported in detail elsewhere. ${ }^{4}$ Therefore, this discussion will focus on differences in genotypic characteristics. The findings are grouped based on genes associated with membership in the Mild Arm Pain class, genes associated with membership in the Moderate Arm Pain class, and genes associated with membership in both persistent pain classes.

## Genes Associated with Membership in the Mild Arm Pain class

Only one gene, namely TH, was uniquely associated with membership in the Mild Arm Pain class. TH is the enzyme that converts tyrosine to dopamine (DA). Mutations in the TH gene are associated with DA-related conditions, as well as psychiatric disorders (e.g., schizophrenia). ${ }^{40}$ While the enzyme itself is not involved in pain, its effects on DA could influence pain mechanisms. Endogenous opioids are released in response to a noxious stimulus, stimulating the release of DA. ${ }^{41}$ Stimulation of the DA receptors results in inhibition of nociception. In a review of the effects of DA, ${ }^{41}$ studies of healthy samples found that participants with lower baseline levels of DA reported higher pain ratings during noxious stimulation. A higher level of DA during the noxious stimulus was associated with lower ratings of pain. DA levels and presynaptic activity has been examined in the setting of chronic pain (i.e., burning mouth syndrome and fibromyalgia). However, the study samples were small and the results are difficult to interpret. In a spared nerve injury (SNI) model of neuropathic pain that is used in rats to mimic neuropathic pain, the application of a DA-receptor agonist had an analgesic effect, while the application of a DA-receptor antagonist reversed this effect. ${ }^{42}$ These results support DA-mediated antinociception in the experience of neuropathic pain.

In the current study, carrying one or two doses of the rare C allele at TH rs2070762 was associated with a 2.39 -fold increase in the odds of belonging to the Mild Arm Pain class. While in one study, this polymorphism was associated with migraines, ${ }^{43}$ this finding was not confirmed in a validation cohort.

## Genes Associated with Membership in the Moderate Arm Pain class

Four genes, namely NOS2A, SLC6A1, TACR1, and NPY, were associated with membership in the Moderate Arm Pain class. NOS2A produces inducible nitric oxide (iNOS), a free radical, as an immune defense mechanism in response to tissue injury. Studies of skeletal muscle and peripheral nerve function have implicated iNOS in ischemia. Of note, inhibition of iNOS leads to improvements in the microcirculation and restitution of motor function. ${ }^{44}$ In one preclinical study of neuropathic pain, ${ }^{45}$ the administration of nitric oxide synthase inhibitors increased the analgesic effects of morphine.

In our study, patients who were heterozygous or homozygous for the rare A allele in NOS2A rs2248814 had a $66 \%$ decreased likelihood of belonging to the Moderate Arm Pain class. NOS2A rs2248814 is located in the intron of the gene. While no studies were identified that evaluated this SNP in the context of persistent pain, associations were found with macular degeneration ${ }^{46}$ and Parkinson's disease. ${ }^{47}$ In one study, ${ }^{46}$ an interaction was found between this SNP, smoking behavior, and the risk for macular degeneration. Specifically, individuals who were heterozygous or homozygous for the rare A allele and who smoked had an increased odds of developing age-related macular degeneration. In contrast, in a study of the association between this SNP and Parkinson's disease, ${ }^{47}$ while a significant association was found between NOS2A rs2248814 and the occurrence of sporadic Parkinson's disease, no gene x smoking interaction was identified. Ayala-Haedo et al. ${ }^{46}$ hypothesized that these inconsistent findings may be due to linkage disequilibrium, as the AA genotype is rare. When examining our findings in light of previous research, the presence of the rare A allele at rs2248814 may be associated
with decreased expression of NOS2A and iNOS, which may prevent nerve injury and associated neuropathic pain.

Gamma-aminobutyric acid (GABA) is the primary inhibitory neurotransmitter in the CNS. GABA is implicated in a large number of disease states including anxiety and stress disorders, insomnia, epilepsy, cognitive and learning deficits, and pain. ${ }^{48}$ GABA transporters clear GABA from the synapse, which regulates pain transmission. The primary transporter of GABA is GABA-transporter 1 (GAT-1). GAT-1 is encoded by the gene SLC6A1. Studies of GAT inhibitors ${ }^{49}$ and GAT-1 knock-out mice ${ }^{50}$ support a relationship between suppressed GAT-1 activity and higher levels of pain.

In our study, individuals who were homozygous for the rare T allele at SLC6A1 rs2601126 had a 3-fold increase in the likelihood of belonging to the Moderate Arm Pain class. This intronic SNP has no known function. Only two studies were identified that examined this polymorphism, focusing on its role in anxiety disorders. ${ }^{51,52}$ In a case-control study of patients with anxiety disorders who did and did not have subsyndromal panic attacks, ${ }^{52}$ no association was found with this SNP. In another study that evaluated the effects of kava, a plant-based medicine, in patients with generalized anxiety disorder (GAD), ${ }^{51}$ for patients who received kava, each dose of the rare T allele was associated with significant decreases in patients' anxiety scores. Kava is known to effect anxiolytic activity from the effects of kavalactone constituents on GABA pathways. Findings from the study by Sarris et al. ${ }^{53}$ suggest that polymorphism in SLC6A1 rs2601126 influences the transport of GABA and results in decreased anxiety. No studies were found that evaluated the relationship between polymorphisms in this SNP and persistent pain.

The neurokinin-1 receptor (NK1 receptor) is the primary target for Substance P and has a unique role in the development of persistent pain. Substance $P$ is a tachykinin, released in the presence of a noxious stimulus. Binding of Substance $P$ to the NK1 receptor increases the excitability of afferent neurons. Through NK1 receptor stimulation, a-amino-3-hydroxy-5-methyl-

4-isoxazolepropionic acid (AMPA) and N-methyl-D-aspartate (NMDA) receptors are sensitized to glutamate, and cyclooxygenase (COX) synthesis of prostaglandin is promoted, which increases neurotransmitter release. ${ }^{54}$ Rat studies found that the NK1 receptor is upregulated in the setting of nerve damage and persistent pain. ${ }^{5,55}$ Prolonged stimulation with a noxious stimulus results in sustained binding of Substance $P$ to the NK1 receptors. ${ }^{54}$ Through these processes, Substance P and NK1 receptors perpetuate neuropathic pain.

In the current study, patients who carried one or two doses of the rare G allele at rs4439987 had a 60\% decrease in the odds of belonging to the Moderate Arm Pain class. While TACR1 rs4439987 was evaluated in a study of alcohol dependence in Caucasians, ${ }^{56}$ no associations were identified. This intronic SNP has not been studied in patients with acute or chronic pain.

The NPY gene encodes for NPY. Present on GABAergic neurons, NPY receptors (i.e., $Y_{1}$ and $Y_{2}$ ) are implicated in the inhibition of acute, inflammatory, and neuropathic pain states. ${ }^{57}$ In animal models, reorganization of sensory pathways and upregulation of NPY occur after nerve injury. ${ }^{5,57}$ In a mouse study, ${ }^{58}$ the administration of NPY antagonists after nerve injury resulted in the resolution of behavioral signs of pain. The administration of NPY agonists restored signs of inflammatory and neuropathic pain. Escalation of receptor activation may lead to inhibition of GABA and glycine release through binding to $\mathrm{Y}_{1}$ receptors and inhibition of excitatory neurotransmitter release through $Y_{2}$ receptor binding. The overall result is inhibition of spinal nociceptive transmission and inhibition of hyperalgesia, which prevents the transition from acute pain to chronic pain.

In the current study, carrying one or two doses of the rare C allele at NPY rs16148 was associated with a 2.70 -fold increase in the odds of belonging to the Moderate Arm Pain class. This intronic SNP was not associated with the occurrence of atherosclerosis. ${ }^{59}$ Solway et al. ${ }^{58}$ inferred that failure of NPY upregulation after injury would cause susceptibility to chronic pain. Based on what is known about NPY and chronic pain, this hypothesis may explain the
association between the rs16148 polymorphism and membership in the Moderate Arm Pain group.

## Genes Associated with Membership in Both the Mild and Moderate Arm Pain classes

Four genes, namely, BDNF, COMT, HTR2A, and HTR3A, were associated with membership in both the Mild and Moderate Arm Pain classes. BDNF has effects throughout the nervous system. BDNF is upregulated in the dorsal root ganglion during states of inflammation or injury. In persistent pain conditions, release of BDNF promotes excitatory, glutamatergic synaptic transmissions, which leads to central sensitization and hyperalgesia. In addition, BDNF suppresses the activity of inhibitory, GABAergic synapses. ${ }^{60}$

Consistent with previous reports of its role in the development of persistent pain, ${ }^{61,62}$ two SNPs in BDNF remained significant after analysis: one in the Mild Arm Pain class (i.e., rs11030102) and one in the Moderate Arm Pain class (i.e., rs2049046). In our study, being heterozygous or homozygous for the G allele in BDNF rs11030102 was associated with a $64 \%$ decrease in the odds of belonging to the Mild Arm Pain class. This finding is consistent with work by Terracciano and colleagues, ${ }^{63}$ who reported that individuals who carried the C allele for rs11030102 had higher serum levels of BDNF. These findings suggest that the $G$ allele at rs11030102 may decrease BDNF expression and reduce the excitatory effects associated with release of this neurotransmitter.

Another polymorphism in the BDNF gene (i.e., rs2049046) was associated with membership in the Moderate Arm Pain class. Patients who were homozygous for the rare T allele were three times more likely to be in the Moderate Arm Pain class. An association between rs2049046 and an increased susceptibility to migraine was found in a retrospective study. ${ }^{64}$ While no differences were found between cases and controls for the BDNF SNP alone, a significant interaction was found between the AT genotype in BDNF rs2049046 and a SNP in the calcitonin gene-related peptide gene (i.e., GC genotype in CGRP rs1553005).

COMT is an enzyme that is responsible for the metabolism of epinephrine, norepinephrine, and DA. Associations between polymorphisms in the COMT gene and pain mechanisms and management have been the subjects of intense investigations (for reviews see ${ }^{9,65}$ ). The results of a recent meta-analysis that focused primarily on studies of COMT rs4680 (Val158Met) $)^{9}$ found a significant association between this SNP and fibromyalgia. In addition, the authors noted that COMT activity does not affect neuropathic or cancer pain. However, a decrease in COMT activity appears to enhance the efficacy of opioid analgesics and exacerbates the adverse effects of opioids in some patients with cancer. They acknowledged that the role of COMT in pain mechanisms and analgesic responses is extremely complex.

In our study, patients who were homozygous for the rare T allele in COMT rs4633 had a $68 \%$ decrease in the odds of belonging to the Mild Arm Pain class. In addition, women who were homozygous for the rare G allele in rs165656 had a $63 \%$ decrease in the odds of belonging in the Moderate Arm Pain class. Located in exon 3 of the COMT gene, rs4633 is a nonsynonymous SNP which was linked to pediatric postoperative pain, ${ }^{66}$ pain after a motor vehicle accident, ${ }^{67}$ pain associated with lumbar disc disease, ${ }^{68}$ pain after lumbar spine surgery, ${ }^{69}$ fibromyalgia, ${ }^{70,71}$ pain in women with major depressive disorder, ${ }^{72}$ and low back pain. ${ }^{73}$

Most often, rs4633 is studied as part of a haplotype. In combination with polymorphisms in rs6269, rs4818, and rs4680 (i.e. Val/Met), rs4633 was associated with low, average, and high pain sensitivity (i.e., LPS, APS, HPS, respectively) phenotypes. COMT rs4680 is the only SNP in this haplotype that changes an amino acid sequence and resulting protein. While in the bivariate analyses, the APS haplotype was significant for Mild Arm Pain and the APS and HPS haplotypes were significant for Moderate Arm Pain, these associations did not remain significant in the multivariate analyses.

While our results suggest a protective effect associated with the TT genotype at rs4633, as part of the COMT haplotype, the T allele at rs4633 is associated with APS. Conflicting evidence exists on the role of COMT rs4633 in pain. For example, in one study that evaluated
the frequency of the COMT haplotype in chronic widespread pain, ${ }^{74}$ no differences in genotype frequencies were found between cases and controls. In another study, ${ }^{75}$ the COMT haplotype was not associated with experimental pain thresholds in a sample of Chinese men.

The only study of COMT rs $165656,{ }^{76}$ evaluated a sample of 44 patients with temporomandibular disorder (TMD) compared to healthy controls ( $\mathrm{n}=182$ ). Being heterogeneous for the $G$ allele (likely referred to as the " $C$ " allele in ${ }^{76}$ ) at rs165656, located in the promoter region of the COMT gene, was associated with an $80 \%$ decrease in the likelihood of having TMD ( $p=.001$ ). This finding appears similar to our results, where the GG genotype at rs165656 was associated with a significant decrease in the likelihood of belonging to the Moderate Arm Pain class. Further study of the rs165656 in concordance with other polymorphisms in the COMT gene may increase our understanding of these results, as with the well-known haplotype associated with rs4633.

The HTR2A gene codes the $5 \mathrm{HT}_{2 \mathrm{~A}}$ receptor. This receptor is highly expressed in dorsal root ganglion cells. In addition, $5 \mathrm{HT}_{2 \mathrm{~A}}$ receptors are located in laminae I-IV of the dorsal horn, and in the nucleus raphe magnus, the thalamus, the cerebral cortex, and the limbic system. In the periphery, activation of $5 \mathrm{HT}_{2 \mathrm{~A}}$ receptors during inflammation results in inhibition of sensitization of primary afferent neurons. In the spinal cord, the function of $5 \mathrm{HT}_{2 \mathrm{~A}}$ receptors, particularly in neuropathic pain, is not well understood.

In the current study, polymorphisms in $5 \mathrm{HT}_{2 \mathrm{~A}}$ were associated with membership in both the Mild and Moderate Arm Pain classes. In the No Arm Pain versus Mild Arm Pain analysis, for the HTR2A Haplotype B02, that is composed of alleles at two SNPs (i.e., rs1923886 [T common allele], rs7330636 [T rare allele]), each additional dose of HTR2A HapB02 was associated with a $51 \%$ decrease in the odds of belonging to the Mild Arm Pain class ( $p=.008$ ). For Moderate Arm Pain, carrying two doses of the rare C allele at HTR2A rs2770298 was associated with a 5.08-fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.028$ ). In
addition, carrying one or two doses of the rare T allele at HTR2A rs9534511 was associated with a 1.89 -fold increase in the odds of belonging to the Moderate Arm Pain class ( $p=.019$ ).

Our findings are consistent with a study of patients with chronic widespread pain (CWP) who were classified using the American College of Rheumatology's criteria. ${ }^{77}$ This study used a discovery cohort (i.e., a population-based cohort of men and women from the Epidemiology of Functional Disorders (EPIFUND) study) and a validation cohort (i.e., a population-based cohort of men from the European Male Aging Study (EMAS)) to evaluate genetic associations with two phenotypes (i.e., CPW and maximum number of pain sites reported). One SNP in HTR2A (i.e., rs12584920) was associated with an increased odds of refractory CWP in both cohorts. In addition, HTR2A rs17289394 was associated with an increase in the odds of reporting a higher number of painful sites in both cohorts. In contrast to our data, HTR2A rs9534511 was associated with a decrease in the odds of reporting a higher number of painful sites. The authors suggested that the HTR2A receptor is involved in the development of musculoskeletal pain. The inconsistent findings may be related to differences in the pain phenotypes evaluated in the two studies.

The $5 \mathrm{HT}_{3}$ receptor is involved in pain, anxiety, and immunomodulatory processes. Located on primary afferent neurons, $5 \mathrm{HT}_{3}$ receptors in the peripheral nervous system alter pain transmission from the periphery. ${ }^{78,79}$ Within the dorsal horn, the activation of $5 \mathrm{HT}_{3}$ receptors is associated with antinociceptive activity during acute pain. Stimulation of these receptors is thought to induce the release of GABA, which activates descending inhibitory pathways. The activation of this descending inhibitory system decreases sensory input from the peripheral nervous system.

Within the central nervous system, $5 \mathrm{HT}_{3}$ receptors are primarily located pre-synaptically and influence the release of neurotransmitters and neuropeptides. ${ }^{78}$ In the setting of chronic pain, $5 \mathrm{HT}_{3}$ receptor antagonists inhibit the release of neurotransmitters like Substance P , neurokinin A, and calcitonin gene-related peptide from primary afferent neurons. In particular,

Substance P is implicated in the development of inflammation and chronic pain. $5 \mathrm{HT}_{3}$ receptor antagonists have been evaluated as treatments for chronic pain syndromes, including fibromyalgia and chronic back pain with positive results. ${ }^{80}$ Inhibition of Substance $P$ release may explain the analgesic effects of $5 \mathrm{HT}_{3}$ receptor antagonists. ${ }^{78}$

In the current study, carrying two doses of the rare A allele at HTR3A rs1985242 was associated with a 90\% decrease in odds of belonging to Mild Arm Pain class. Carrying two doses of the rare A allele at HTR3A rs1985242 was associated with an $85 \%$ decrease in the odds of belonging to the Moderate Arm Pain class. The HTR3A gene encodes for the $5 \mathrm{HT}_{3}$ serotonin receptor. This intronic SNP has not been implicated in other persistent pain conditions.

Several study limitations need to be acknowledged. The sample was adequate in size and representative of breast cancer patients in the United States. However, additional latent classes and significant neurotransmitter gene polymorphisms may have been defined from a larger, more diverse sample, including a larger percentage of non-white, older patients, or those who had more advanced disease or more extensive surgery. This study was limited to the selected candidate genes. As technology evolves, examination of the full genome may elucidate additional genes and polymorphisms associated with persistent pain. Additionally, serum levels of the various neurotransmitters were not measured to support the gene associations that were identified. Patients were recruited through referrals from twenty surgeons at seven different sites, to enhance generalizability of the study's findings. Evaluating how surgical and postoperative pain management protocols impact persistent postoperative pain and SNP interactions will add another dimension to future studies.

This study is the first prospective, longitudinal study to examine the prevalence of persistent arm pain following breast cancer surgery and its association with neurotransmitter genes. The elucidation of genetic factors that predispose patients to persistent arm pain will
change how we treat breast cancer patients and improve postoperative outcomes. Further study is needed to confirm our findings in varied populations and in other persistent pain conditions.

## DISCLOSURES

This study was funded by grants from the National Cancer Institute (CA107091 and CA118658).
Dr. Dhruva is funded through an NIH Mentored Patient-Oriented Research Career Development Award (K23 AT005340). Dr. Langford is supported by a Breast Cancer Research Program Department of Defense Postdoctoral Fellowship. Dr. Leutwyler is supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through UCSF-CTSI Grant Number KL2TR000143. Dr. Miaskowski is an American Cancer Society Clinical Research Professor. This project is supported by NIH/NCRR UCSF-CTSI Grant Number UL1 RR024131. Its contents are solely the responsibility of the authors and do not necessarily represent the official views of the NIH. No conflicts of interest exist.

Multiple logistic regression analyses of candidate gene associations with no arm pain versus mild arm pain classes ( $n=196$ ). For each model, the first three principal components identified from the analysis of ancestry informative markers, as well as self-reported race/ethnicity, were retained in all models to adjust for potential confounding due to race/ethnicity (data not shown). For the regression analyses, predictors evaluated in each model included: genotype (BDNF rs11030102: CC versus CG+GG; COMT rs4633: CC+CT versus TT; HTR2A HapB02 composed of the rs1923886 common T allele and the rs7330636 rare T allele; HTR3A rs1985242: TT+TA versus AA; TH rs2070762: TT versus TC+CC), functional status (KPS score in 10 unit increments), pain in the affected breast prior to surgery, and undergoing an axillary lymph node dissection.

Abbreviations: ALND = axillary lymph node dissection; BDNF = brain derived neurotrophic factor; $\mathrm{Cl}=$ confidence interval; COMT= catechol-O-methyltransferase; Hap = haplotype; HTR2A = 5-
hydroxytryptamine receptor 2A, G protein coupled; HTR3A $=5$-hydroxytryptamine receptor 3A, ionotropic; KPS = Karnofsky Performance Status; TH = tyrosine hydroxylase

Table 5 - Multiple Logistic Regression Analyses for Neurotransmitter Genes and None Versus Moderate Arm Pain

| Predictor | Odds Ratio | Standard Error | 95\% CI | Z | p-value |

Multiple logistic regression analyses of candidate gene associations with no arm pain versus moderate arm pain classes ( $\mathrm{n}=218$ ). For each model, the first three principal components identified from the analysis of ancestry informative markers, as well as self-reported race/ethnicity, were retained in all models to adjust for potential confounding due to race/ethnicity. For the regression analyses, predictors evaluated in each model included genotype (BDNF rs2049046: AA+AT versus TT; COMT rs165656: CC+CG versus GG; HTR2A rs2770298: TT+ CT versus CC; HTR2A rs9534511: CC versus CT+TT; HTR3A rs1985242: TT+TA versus AA; NOS2A rs2248814: GG versus GA+AA; NPY rs16148: TT versus

## Publishing Agreement

It is the policy of the University to encourage the distribution of all theses, dissertations, and manuscripts. Copies of all UCSF theses, dissertations, and manuscripts will be routed to the library via the Graduate Division. The library will make all theses, dissertations, and manuscripts accessible to the public and will preserve these to the best of their abilities, in perpetuity.

## Please sign the following statement:

I hereby grant permission to the Graduate Division of the University of California, San Francisco to release copies of my thesis, dissertation, or manuscript to the Campus Library to provide access and preservation, in whole or in part, in perpetuity.
