ABSTRACT OF THE THESIS

A Comparative Analysis of Innovative Microchannel Heat Sinks for Electronic Cooling

by

Sainan Lu

Master of Science, Graduate Program in Mechanical Engineering University of California, Riverside, December 2015 Dr. Kambiz Vafai, Chairperson

In this work, a comparative analysis of innovative microchannel heat sinks such as two layered and multilayered microchannel heat sinks (MCHS), or thin films within flexible complex seals and cooling augmentation using microchannels with rotatable separating plates, is presented. A compilation of the numbers of layers, main characteristics, setups, advantages and disadvantages, thermal resistance, pumping power in double-layer(DL-MCHS) and multi-layer MCHS (ML-MCHS) is presented. In addition, the thermal resistance is analyzed in order to present a comparison between the single-layer MCHS (SL-MCHS) and multi-layer microchannels. The results of comparison indicates that double-layer and multilayer MCHS have lower thermal resistance and require smaller pumping power and they resolve the high streamwise temperature rise problem of SL-MCHS.

Keywords: Double-layered Microchannel, Multi-layer Microchannel, Thermal Resistance, Pumping Power

1. Introduction

The heat removal issue has became increasingly important in the electronics applications. In this work innovative microchannels are investigated. Microchannels were first introduced by Tuckerman and Pease[1]. Microchannel heat sinks maximize the surface area, minimize the thermal resistance, and thus increase the heat transfer from the component into the surroundings while offering a compact cooling system.

The large majority of the microchannels studies in the literature are based on the single-layer microchannels. The disadvantage of SL-MCHS is the relatively high streamwise temperature rise which can have an adverse influence on the equipment. This high streamwise temperature rise is caused by heat released by the equipment and carried out by a relatively small amount of coolant, which results a high streamwise temperature. Hence the undesirable high temperature rise causes larger thermal stress, for example, in chips and electronic packages due to the coefficient of thermal expansion mismatch among different materials thus undermining device reliability. In addition, the adverse effects of many electrical parameters are caused by a sharp temperature rise. One way to reduce the undesired temperature rise in the single layered microchannels is to increase the

pumping power, which can generate more noise and require bulkier packaging. This is certainly undesireable.

However, the two-layered microchannel, first established by Vafai and Zhu[2,4], as well as multilayered microchannels also first established by Vafai and Zhu[3], reduce the undesired temperature gradient in the streamwise direction. The design concept is based on a two-fold microchannel structures, one atop another. For such an arrangement, streamwise temperature rise for the coolant and the substrate in each layer are remunerated through conduction between the two layers. Since the temperature gradient is much smaller than the SL-MCHS, the required pressure drop can be substantially smaller than SL-MCHS, which can require a significantly smaller pumping power.

Following the works of Vafai & Zhu[2], [3]&[4] extensive investigations have been conducted regarding the two and multi-layer microchannel heat sinks in order to optimize the configurations and improve the thermal performance for various applications. In this work, studies on ML-MCHS are investigated and synthesized. These are comprehensively summarized in Table 1. In this work, ML-MCHS main characteristics, icon diagram, advantages and disadvantages, thermal resistance and pumping power are characterized. Also the comparisons of thermal resistance and pumping power between the SL-MCHS and ML-MCHS are investigated. Particularly, the thermal resistance is extracted to compare with the SL-MCHS.

2. Analysis

2.1 Thermal Resistance

The overall thermal resistance, which is defined as:

$$Q = KA \frac{\Delta T}{L} = \frac{\Delta T}{R} = qA$$
$$R_{th} = \frac{\Delta T}{qA}$$
$$R_{th} = \frac{T_J - T_{in}}{qA}$$

where T_j is the junction temperature, T_{in} the inlet temperature of coolant, q is the heat flux and A is the base area of the heat sink.

In order to unify the overall thermal resistance, the unit overall thermal resistance is employed when comparing SL-MCHS and ML-MCHS cases.

$$R_{unit} = R_{th}A$$

A wide range of pertinent SL-MCHS cases in the literature are selected and the unit overall thermal resistances are presented in Table 2 in order to establish a reasonable comparison. After arriving at the thermal resistance from the literature, the corresponding average thermal resistance for the SL-MCHS in the literature is calculated. The maximum and the minimum average values are used to find the average value. The final average unit overall thermal resistance for the SL-MCHS is obtained by calculating the average value among all the average values we have calculated.

The average value of the overall thermal resistance can be calculated simply by either :

$$R_{ave} = \frac{R_{max} + R_{min}}{2}$$

or

$$R_{ave} = \frac{R_1 + R_2 + \dots + R_n}{n}$$

2.2 Pumping Power

The pumping power is defined as:

$$\Omega = Q_V \Delta p = u_{in} A_C \Delta p N$$

where Q_V is the volumetric flow rate, Δp the pressure drop, A_C the channel crosssectional area and N is the number of channels.

In order to unify the pumping power, the unit length pumping power is calculated.

$$\Omega_{unit} = \frac{\Omega}{L}$$

where L is the total length of microchannel heat sinks.

3. Results and Discussion

Table 1 presents the synthesis of a wide range of the innovative design heat sink equipments for cooling applications. Also, included is an innovative design for the control of exit flow and thermal conditions using two-layered thin films by flexible complex seals and cooling augmentation using microchannels with rotatable separating plates, which were introduced by Khaled, and Vafai [7, 20]. Their main characteristics, icon diagram, advantages and disadvantages, thermal resistance and pumping power attributes are all illustrated. It should be noted that ML-MCHS reduces the pumping power, anywhere from 29.3% upto 99.9%.

Table 2 shows the pertinent unit overall thermal resistance in single-layer microchannel heat sinks in the literature and their average value. The comparison between the SL-MCHS and ML-MCHS is presented in Table 3. In general, ML-MCHS improves the thermal performance of heat sinks by reducing the overall thermal resistance, and decreases the required pumping power.

Conclusions

Compared to the single-layer microchannel heat sinks, the innovative DL-MCHS and ML-MCHS heat sink designs overcome the drawbacks, and possess attributes that are superior to that of SL-MCHS. ML-MCHS designs reduces the problem of high streamwise temperature rise and they reduce the thermal resistance and pumping power to a large degree. Furthermore, the proposed twolayered thin film supported by flexible complex seals unlike other controlling systems does not require additional mechanical control or external cooling devices. In addition, the DL-flexible microchannels devices are found to provide more cooling effects per unit pumping power than the rigid ones at flow Reynolds numbers below specific values, and at stiffness number and an aspect ratio above certain values.
