Title: Reflective Cracking Study: HVS Test Section Forensic Investigation									
Authors: D. Jones, B. Steven and J. Harvey									
Prepared for: Caltrans		FHWA No: CA091073I		Date: July 2007					
Contract No: 65A0172		Client Reference No: SPE 4.10		Status: Stage 6, Approved Version					
Abstract: This report is one in a series of first-level analysis reports that describe the results of HVS testing on a full-scale experiment being performed at the Richmond Field Station (RFS) to validate Caltrans overlay strategies for the rehabilitation of cracked asphalt concrete. It describes the results of the forensic investigation on the HVS rutting sections (Sections 580RF through 581RF) and HVS reflective cracking testing sections (Sections 586RF through 591RF). The study forms part of Partnered Pavement Research Center Strategic Plan Element 4.10: "Development of Improved Rehabilitation Designs for Reflective Cracking." Findings and observations based on the data collected during this forensic investigation include: • There was considerable variation in the thicknesses of the constructed layers of the test road. • In the rutting experiments, rutting occurred primarily in the underlying DGAC and not in the overlay. In the reflective cracking experiments, rutting occurred in both layers. Very little rutting occurred in the underlying layers. • Cracks were observed on some of the test pit profiles. In the underlying DGAC layer, cracks were generally clearly visible. However, in the overlays, heat generated from the saw cut operation appeared to seal any cracks and no conclusions could be drawn as to the depth that cracks had reflected into the overlays. Most cracks appeared to have initiated close to the bottom of the underlying DGAC. Some crack initiation was also observed at poorly bonded joints between lifts and overlays in the AR4000-D section. • Some post-construction cementation of the base material appeared to have occurred. This was substantiated with DCP tests, close inspection of the test pit profile, use of phenolphthalein to determine the pH of the base material, and examination of specimens under optical and scanning electron microscopes. This recementation appears to have contributed to the good performance of the sections. • Base material density was generally consistent over the section. Nuclear gauge determined wet densities averaged 2,176 kg/m³, which corresponds with the average of 2,200 kg/m³ recorded after construction. • Nuclear gauge-determined base moisture contents averaged 11.1 percent for the 18 test pits, with higher moisture contents in the top 50 mm compared to the remainder of the layer. This is higher than the predetermined optimum (8.9 percent) and the laboratory-determined gravimetric moisture contents (8.7 percent). • Subgrade densities were not measured. The average subgrade moisture content was 15 percent, considerably higher than the base moisture content. The presence of mottling in the subgrade material indicates that the moisture content probably fluctuated seasonally. • Air-void contents were lower in the wheelpath after HVS testing compared to before HVS testing, as expected. The findings of this investigation confirm the conclusions of the other first-level analysis reports on HVS testing. No recommendations as to the use of modified binders in overlay mixes are made at this time.

PROJECT OBJECTIVES

The objective of this project is to develop improved rehabilitation designs for reflective cracking for California.

This objective will be met after completion of four tasks identified by the Caltrans/Industry Rubber Asphalt Concrete Task Group (RACTG):

1. Develop improved mechanistic models of reflective cracking in California.
2. Calibrate and verify these models using laboratory and HVS testing.
3. Evaluate the most effective strategies for reflective cracking.
4. Provide recommendations for reflective cracking strategies.

This document is one of a series addressing Tasks 2 and 3.

ACKNOWLEDGEMENTS

The University of California Pavement Research Center acknowledges the assistance of the Rubber Pavements Association, Valero Energy Corporation, and Paramount Petroleum which contributed funds and asphalt binders for the construction of the Heavy Vehicle Simulator test track discussed in this study.

REFLECTIVE CRACKING STUDY REPORTS

The reports prepared during the reflective cracking study document data from construction, Heavy Vehicle Simulator (HVS) tests, laboratory tests, and subsequent analyses. These include a series of first- and second-level analysis reports and two summary reports. On completion of the study this suite of documents will include:

1. Reflective Cracking Study: Summary of Construction Activities, Phase 1 HVS Testing and Overlay Construction (UCPRC-RR-2005-03)
2. Reflective Cracking Study: First-level Report on the HVS Rutting Experiment (UCPRC-RR-2007-06)
3. Reflective Cracking Study: First-level Report on HVS Testing on Section 590RF — 90 mm MB4-G Overlay (UCPRC-RR-2006-04)
4. Reflective Cracking Study: First-level Report on HVS Testing on Section 589RF — 45 mm MB4-G Overlay (UCPRC-RR-2006-05)
5. Reflective Cracking Study: First-level Report on HVS Testing on Section 587RF — 45 mm RAC-G Overlay (UCPRC-RR-2006-06)
6. Reflective Cracking Study: First-level Report on HVS Testing on Section 588RF — 90 mm AR4000-D Overlay (UCPRC-RR-2006-07)
7. Reflective Cracking Study: First-level Report on HVS Testing on Section 586RF — 45 mm MB15-G Overlay (UCPRC-RR-2006-12)
8. Reflective Cracking Study: First-level Report on HVS Testing on Section 591RF — 45 mm MAC15TR-G Overlay (UCPRC-RR-2007-04)
9. Reflective Cracking Study: HVS Test Section Forensic Report (UCPRC-RR-2007-05)
10. Reflective Cracking Study: First-level Report on Laboratory Fatigue Testing (UCPRC-RR-2006-08)

EXECUTIVE SUMMARY

This report is one in a series of first-level analysis reports that describe the results of HVS testing on a full-scale experiment being performed at the Richmond Field Station (RFS) to validate Caltrans overlay strategies for the rehabilitation of cracked asphalt concrete. It describes the forensic investigation of the HVS rutting and reflective cracking testing sections, designated 580RF through 591RF, carried out on various modified-binder overlays. The testing forms part of Partnered Pavement Research Center Strategic Plan Element 4.10: “Development of Improved Rehabilitation Designs for Reflective Cracking.”

The objective of this project is to develop improved rehabilitation designs for reflective cracking for California. This objective will be met after completion of the following four tasks:

1. Develop improved mechanistic models of reflective cracking in California;
2. Calibrate and verify these models using laboratory and HVS testing;
3. Evaluate the most effective strategies for reflective cracking; and
4. Provide recommendations for reflective cracking strategies.

This report is one of a series addressing Tasks 2 and 3. It consists of three main chapters. Chapter 2 provides information on the experiment layout, pavement design, and HVS test details. Chapter 3 summarizes the forensic investigation procedure, observations and results. Chapter 4 provides a summary and lists key findings.

The underlying pavement was designed following standard Caltrans procedures and it incorporates a 410-mm (16.1 in) Class 2 aggregate base on subgrade with a 90-mm (3.5-in) dense-graded asphalt concrete (DGAC) surface. Design thickness was based on a subgrade R-value of 5 and a Traffic Index of 7 (~121,000 equivalent standard axles, or ESALs). This structure was trafficked with the HVS in 2003 to induce fatigue cracking (Phase 1 HVS testing) then was overlaid with six different treatments to assess their ability to limit reflective cracking. The treatments included:

- Half-thickness (45 mm) MB4 gap-graded overlay (referred to as “45 mm MB4-G” in this report)
- Full-thickness (90 mm) MB4 gap-graded overlay (referred to as “90 mm MB4-G” in this report)
- Half-thickness MB4 gap-graded overlay with minimum 15 percent recycled tire rubber (referred to as “MB15-G” in this report)
- Half-thickness MAC15TR gap-graded overlay with minimum 15 percent recycled tire rubber (referred to as “MAC15-G” in this report)
- Half-thickness rubberized asphalt concrete gap-graded overlay (RAC-G), included as a control for performance comparison purposes (the section discussed in this report)

- Full-thickness (90 mm) AR4000 dense-graded overlay (AR4000-D), included as a control for performance comparison purposes

The thickness for the AR4000-D overlay was determined according to Caltrans Test Method 356. The other overlay thicknesses were either the same or half of the AR4000-D overlay thickness. Details on construction and the first phase of trafficking are provided in an earlier report.

Laboratory fatigue and shear studies are being conducted in parallel with HVS testing. Results of these studies are detailed in separate first-level reports. Comparison of the laboratory and test section performance, including the results of this forensic investigation, will be discussed in a second-level report once all the data from all of the studies has been collected and analyzed.

HVS trafficking on the overlay sections (Phase 2 HVS testing) commenced on September 4, 2003 (Section 580RF), and was completed on June 25, 2007 (Section 591RF). During this period a total of more than 12 million load repetitions (varying from 2,000 repetitions on Section 580RF to 2.55 million on Section 591RF) at loads varying between 60 kN (13,500 lb) and 100 kN (22,500 lb) were applied across the sections, which equates to approximately 366 million ESALs, using the Caltrans conversion of (axle load/18,000lb)^{4.2}. A temperature chamber was used to maintain the pavement temperature at 50°C±4°C (122°F±7°F) on the rutting sections, and at 20°C±4°C (68°F±7°F) for the first one million repetitions, then at 15°C±4°C (59°F±7°F) for the remainder of the test on the reflective cracking sections. A dual-tire configuration (720 kPa [104psi] pressure) was used for all experiments. On the rutting tests, channelized unidirectional loading was applied, while on the reflective cracking sections, bidirectional loading with lateral wander was used.

Findings and observations based on the data collected during this forensic investigation include:

- There was considerable variation in the thicknesses of the base, underlying DGAC, and the overlays over the length and width of the test road.
- In the rutting experiments (Sections 580RF through 585RF), rutting occurred primarily in the underlying DGAC and not in the overlay. On the reflective cracking experiments (Sections 586RF through 591RF), rutting occurred in both layers. Rutting from the Phase 1 trafficking was clearly visible on most test pit profiles. Very little rutting occurred in the base and no rutting was recorded in the subgrade. This corresponds to the Multi-Depth Deflectometer permanent deformation analyses discussed in the first-level reports on each section.
- Cracks were observed on some of the test pit profiles. In the underlying DGAC layer, cracks were generally clearly visible. However, in the overlays, heat generated from the saw cut

operation appeared to seal any cracks and no conclusions could be drawn as to the depth that cracks had reflected into the overlays. Most cracks appeared to have initiated close to the bottom of the underlying DGAC. Some crack initiation was also observed at poorly bonded joints between lifts and overlays in the AR4000-D section (Section 588RF). No additional information was gathered from an assessment of cores. No cracking was observed in the base.

- Some post-construction cementation of the base material appeared to have occurred. This was substantiated with Dynamic Cone Penetrometer (DCP) tests, close inspection of the test pit profile, the use of phenolphthalein to determine the pH of the base material, and examination of specimens under optical and scanning electron microscopes. This recementation appears to have contributed to the good performance of the sections.
- Densities were generally consistent throughout the section. Nuclear gauge determined wet densities averaged 2,176 kg/m³ (standard deviation of 34 kg/m³ [135.8 pcf, standard deviation of 2.1 pcf), which corresponds with the average wet density of 2,200 kg/m³ (137.3 pcf) for the road base recorded after construction.
- Nuclear gauge determined moisture contents averaged 11.1 percent (standard deviation of 1.1 percent) for the eighteen test pits. In most test pits, the moisture content in the upper 50 mm (2 in) was on the order of one percent higher than in the material between 150 mm (6 in) and 200 mm (8 in). The optimum moisture content of the Class 2 aggregate base material, determined prior to construction, was 8.9 percent, somewhat lower than the average recorded with the nuclear gauge. Laboratory-determined gravimetric moisture contents averaged 8.7 percent, which was closer to the optimum moisture content.
- Subgrade densities were not measured. The average subgrade moisture content was 15 percent (lowest of 12.9 percent and highest of 18.0 percent), considerably higher than the base moisture content. The presence of mottling in the subgrade material indicates that the moisture content probably fluctuated seasonally.
- The air-void contents of cores removed from the wheelpaths in the reflective cracking sections after HVS testing were lower compared to those determined from cores removed from outside the sections prior to HVS testing, as expected.

The findings of this investigation confirm the conclusions drawn from analyses of data collected from the instrumentation during HVS testing and documented in the first-level analysis reports.

No recommendations as to the use of modified binders in overlay mixes are made at this time. These recommendations will be included in the second-level analysis report, which will be prepared and submitted on completion of all data analysis.

1. INTRODUCTION

1.1. Objectives

The first-level analysis presented in this report is part of Partnered Pavement Research Center Strategic Plan Element 4.10 (PPRC SPE 4.10) being undertaken for the California Department of Transportation (Caltrans) by the University of California Pavement Research Center (UCPRC). The objective of the study is to evaluate the reflective cracking performance of asphalt binder mixes used in overlays for rehabilitating cracked asphalt concrete pavements in California. The study includes mixes modified with rubber and polymers, and it will develop tests, analysis methods, and design procedures for mitigating reflective cracking in overlays. This work is part of a larger study on modified binder (MB) mixes being carried out under the guidance of the Caltrans Pavement Standards Team (PST) (1), which includes laboratory and accelerated pavement testing using the Heavy Vehicle Simulator (carried out by the UCPRC), and the construction and monitoring of field test sections (carried out by Caltrans).

1.2. Overall Project Organization

This UCPRC project is a comprehensive study, carried out in three phases, involving the following primary elements (2):

- Phase 1
 - The construction of a test pavement and subsequent overlays;
 - Six separate Heavy Vehicle Simulator (HVS) tests to crack the pavement structure;
 - Placing of six different overlays on the cracked pavement;
- Phase 2
 - Six HVS tests to assess the susceptibility of the overlays to high-temperature rutting (Phase 2a);
 - Six HVS tests to determine the low-temperature reflective cracking performance of the overlays (Phase 2b);
 - Laboratory shear and fatigue testing of the various hot-mix asphalts (Phase 2c);
 - Falling Weight Deflectometer (FWD) testing of the test pavement before and after construction and before and after each HVS test;
 - Forensic evaluation of each HVS test section;
- Phase 3
 - Performance modeling and simulation of the various mixes using models calibrated with data from the primary elements listed above.

Phase 1

In this phase, a conventional dense-graded asphalt concrete (DGAC) test pavement was constructed at the Richmond Field Station (RFS) in the summer of 2001. The pavement was divided into six cells, and within each cell a section of the pavement was trafficked with the HVS until the pavement failed by either fatigue (2.5 m/m^2 [0.76 ft/ft²]) or rutting (12.5 mm [0.5 in]). This period of testing began in the summer of 2001 and was concluded in the spring of 2003. In June 2003 each test cell was overlaid with either conventional DGAC or asphalt concrete with modified binders as follows:

- Full-thickness (90 mm) AR4000-D dense-graded asphalt concrete overlay, included as a control for performance comparison purposes (AR-4000 is approximately equivalent to a PG64-16 performance grade binder);
- Full-thickness (90 mm) MB4-G gap-graded overlay;
- Half-thickness (45 mm) rubberized asphalt concrete gap-graded overlay (RAC-G), included as a control for performance comparison purposes;
- Half-thickness (45 mm) MB4-G gap-graded overlay;
- Half-thickness (45 mm) MB4-G gap-graded overlay with minimum 15 percent recycled tire rubber (MB15-G), and
- Half-thickness (45 mm) MAC15-G gap-graded overlay with minimum 15 percent recycled tire rubber.

The conventional overlay was designed using the current (2003) Caltrans overlay design process. The various modified overlays were either full (90 mm) or half thickness (45 mm). Mixes were designed by Caltrans. The overlays were constructed in one day.

Phase 2

Phase 2 included high-temperature rutting and low-temperature reflective cracking testing with the HVS as well as laboratory shear and fatigue testing. The rutting tests were started and completed in the fall of 2003. For these tests, the HVS was placed above a section of the underlying pavement that had not been trafficked during Phase 1. A reflective cracking test was next conducted on each overlay from the winter of 2003-2004 to the summer of 2007. For these tests, the HVS was positioned precisely on top of the sections of failed pavement from the Phase 1 HVS tests to investigate the extent and rate of crack propagation through the overlay.

In conjunction with Phase 2 HVS testing, a full suite of laboratory testing, including shear and fatigue testing, was carried out on field-mixed, field-compacted; field-mixed, laboratory-compacted; and laboratory-mixed, laboratory-compacted specimens.

Phase 3

Phase 3 entailed a second-level analysis carried out on completion of HVS and laboratory testing (the focus of this report). This included extensive analysis and characterization of the mix fatigue and mix shear data, backcalculation of the FWD data, performance modeling of each HVS test, and a detailed series of pavement simulations carried out using the combined data.

An overview of the project timeline is shown in Figure 1.1.

Figure 1.1: Timeline for the Reflective Cracking Study.

Reports

The reports prepared during the reflective cracking study document data from construction, HVS tests, laboratory tests, and subsequent analyses. These include a series of first- and second-level analysis reports and two summary reports. On completion of the study this suite of documents will include:

- One first-level report covering the initial pavement construction, the six initial HVS tests, and the overlay construction (Phase 1);
- One first-level report covering the six Phase 2 rutting tests (but offering no detailed explanations or conclusions on the performance of the pavements);
- Six first-level reports, each of which covers a single Phase 2 reflective cracking test (containing summaries and trends of the measured environmental conditions, pavement responses, and pavement performance but offering no detailed explanations or conclusions on the performance of the pavement);
- One first-level report covering laboratory shear testing;
- One first-level report covering laboratory fatigue testing;
- One report summarizing the HVS test section forensic investigation;
- One report summarizing the backcalculation analysis of deflection tests,

- One second-level analysis report detailing the characterization of shear and fatigue data, pavement modeling analysis, comparisons of the various overlays, and simulations using various scenarios (Phase 3), and
- One four-page summary report capturing the conclusions and one longer, more detailed summary report that covers the findings and conclusions from the research conducted by the UCPRC.

1.3. Structure and Content of This Report

This report presents the results of a forensic investigation on HVS test sections 580RF through 591RF and is organized as follows:

- Chapter 2 contains a description of the HVS test program.
- Chapter 3 presents a summary of the forensic investigation procedure and discussion of the observations and test results collected.
- Chapter 4 contains a summary of the results together with conclusions and observations.

A second-level analysis report will be prepared upon completion of all the testing and data analysis exercises and will include a comparison of the performance of the various sections and a comparison of those results with laboratory test data, as well as simulations with different climate, traffic and pavement structures.

1.4. Measurement Units

Metric units have always been used in the design and layout of HVS test tracks, and for all the measurements, data storage, analysis, and reporting at the eight HVS facilities worldwide (as well as all other international accelerated pavement testing facilities). Continued use of the metric system facilitates consistency in analysis, reporting, and data sharing.

In this report, metric and English units are provided in the Executive Summary, Chapters 1 and 2, and the Conclusion. In keeping with convention, only metric units are used in Chapter 3. A conversion table is provided on Page iv at the beginning of this report.

2. TEST DETAILS

2.1. Experiment Layout

Six overlays were constructed as part of the second phase of the study as follows, each with a rutting test section and a reflective cracking test section. These sections and the corresponding Phase 1 fatigue test sections are shown in Figure 2.1.

1. Sections 580RF and 586RF: Half-thickness (45 mm) MB4 gap-graded overlay with minimum 15 percent recycled tire rubber (referred to as “MB15-G” in this report);
2. Sections 581RF and 587RF: Half-thickness (45 mm) rubberized asphalt concrete gap-graded (RAC-G) overlay;
3. Sections 582RF and 588RF: Full-thickness (90 mm) AR4000 dense-graded asphalt concrete overlay (designed using CTM356 and referred to as “AR4000-D” in this report);
4. Sections 583RF and 589RF: Half-thickness (45 mm) MB4 gap-graded overlay (referred to as “45 mm MB4-G” in this report);
5. Sections 584RF and 590RF: Full-thickness (90 mm) MB4 gap-graded overlay (referred to as “90 mm MB4-G” in this report), and
6. Sections 585RF and 591RF: Half-thickness (45 mm) MAC15TR gap-graded overlay with minimum 15 percent recycled tire rubber (referred to as “MAC15-G” in this report).

2.2. Test Section Layout

The general test section layout for each section is shown in Figure 2.2. Station numbers refer to fixed points on the test section and are used for measurements and as a reference for discussing performance.

2.3. Underlying Pavement Design

The pavement for the first phase of HVS trafficking was designed according to the Caltrans Highway Design Manual Chapter 600 using the computer program *NEWCON90*. Design thickness was based on a tested subgrade R-value of 5 and a Traffic Index of 7 (~121,000 ESALs) (3).

The pavement design for the test road and as-built pavement structure for the overlay sections (580RF through 591RF), determined from cores removed from the edge of the sections, are illustrated in Figure 2.3.

Figure 2.1: Layout of Reflective Cracking Study project.

Figure 2.2: Test section layout.

Design	580RF/586RF	581RF/587RF	582RF/588RF	583RF/589RF	584RF/590RF	585RF/591RF
Overlay (45 or 90 mm)	MB15-G (46 mm)	RAC-G (50 mm)	AR4000-D (94 mm)	MB4-G (48 mm)	MB4-G (91 mm)	MAC15-G (45 mm)
DGAC (90 mm)	DGAC (81 mm)	DGAC (81 mm)	DGAC (93 mm)	DGAC (77 mm)	DGAC (88 mm)	DGAC (110 mm)

Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)	Clay subgrade (semi-infinite)

Figure 2.3: Pavement design for Reflective Cracking Study experiment (design and actual).

The existing subgrade was ripped and reworked to a depth of 200 mm (8 in) so that the optimum moisture content and the maximum wet density met the specification per Caltrans Test Method CTM 216. The average maximum wet density of the subgrade was 2,180 kg/m³ (136 pcf). The average relative compaction of the subgrade was 97 percent (3).

The aggregate base was constructed to meet the Caltrans compaction requirements for aggregate base Class 2 using CTM 231 nuclear density testing. The maximum wet density of the base determined according to CTM 216 was 2,200 kg/m³ (137 pcf). The average relative compaction was 98 percent.

The DGAC layer consisted of a dense-graded asphalt concrete (DGAC) with AR-4000 binder and aggregate gradation limits following Caltrans 19-mm (0.75 in) maximum size coarse gradation (3). The target asphalt content was 5.0 percent by mass of aggregate, while actual contents varied between 4.34 and 5.69 percent. Nuclear density measurements and extracted cores were used to determine a preliminary as-built mean air-void content of 9.1 percent with a standard deviation of 1.8 percent. The based was primed before placing the asphalt concrete.

2.4. Summary of Testing on the Underlying Layer

Phase 1 trafficking took place between December 21, 2001, and March 25, 2003, and is summarized in Table 2.1. Figure 2.4 presents the final cracking patterns of each section after testing.

Table 2.1: Summary of Testing on the Underlying DGAC Layer

Section	Start date	End date	Repetitions	Wheel Load (kN)	Wheel	Tire Pressure (kPa)	Direction
567RF	12/21/01	01/07/02	78,500	60 ¹	Dual	720 ²	Bi
568RF	01/14/02	02/12/02	377,556	60	Dual	720	Bi
569RF	03/25/03	04/11/03	217,116	60	Dual	720	Bi
571RF	07/12/02	10/02/02	1,101,553	60	Dual	720	Bi
572RF	01/23/03	03/12/03	537,074	60	Dual	720	Bi
573RF	03/18/02	03/08/02	983,982	60	Dual	720	Bi
¹ - 13,500 lb				² - 104 psi			

Figure 2.4: Cracking patterns and rut depths on Sections 569RF through 573RF after Phase 1.

2.5. Overlay Design

The overlay thickness for the experiment was determined according to Caltrans Test Method CTM 356 using Falling Weight Deflectometer data from the Phase 1 experiment.

Laboratory testing was carried out by Caltrans and UCPRC on samples collected during construction to determine actual binder properties, binder content, aggregate gradation, and air-void content. The binders met requirements, based on testing performed by Caltrans. The average ignition-extracted binder contents of the various layers, corrected for aggregate ignition and compared to the design binder content are listed in Table 2.2. For each section, actual binder contents were higher than design contents. It is not clear whether this is a function of the test or contractor error.

Table 2.2: Design versus Actual Binder Contents

Section	Mix	Binder content (%)	
		Design	Actual
580RF and 586RF	MB15-G	7.1	7.52
581RF and 587RF	RAC-G	8.0	8.49
582RF and 588RF	AR4000-D	5.0	6.13
583RF and 589RF	MB4-G (45mm)	7.2	7.77
584RF and 590RF	MB4-G (90mm)	7.2	7.77
585RF and 591RF	MAC15-G	7.4	7.55

The aggregate gradations for the dense- and gap-graded mixes generally met Caltrans specifications for 19.0 mm (0.75 in.) maximum size coarse and gap gradations respectively, with specifics for each section detailed below. Gradations are illustrated in Figures 2.5 (AR4000-D) and 2.6 (modified binders).

- 580RF and 586RF: Material passing the 6.35 mm (1/4 in), 9.5 mm (3/8 mm), 12.5 mm (1/2 in) and 19.0 mm (3/4 in) sieves was on the lower envelope limit (Figure 2.6).
- 581RF and 587RF: Material passing the 0.3 mm (#50), 0.6 mm (#30) and 2.36 mm (#8) sieves was on the upper envelope limit (Figure 2.6).
- 582RF and 588RF: Material passing the 0.6 mm (#30), 2.36 mm (#8) and 4.75 mm (#4) sieves was on the upper envelope limit (Figure 2.5).
- 583RF and 589RF: Material passing the 6.35 mm (1/4 in) and 9.5 mm (3/8 in) sieves was on the lower envelope limit (Figure 2.6).
- 584RF and 590RF: Material passing the 6.35 mm (1/4 in) and 9.5 mm (3/8 in) sieves was on the lower envelope limit (Figure 2.6).
- 585RF and 591RF: Material passing the 0.6 mm (#30), 9.5 mm (3/8 in), 12.5 mm (1/2 in) and 19.0 mm (3/4 in) sieves was on the upper envelope limit, while material passing the 2.36 mm (#8), 4.75 mm (#4) and 6.35 mm (1/4 in) sieves was outside the upper limit (Figure 2.6).

Figure 2.5: Gradation for AR4000-D overlay.

Figure 2.6: Gradation for modified binder overlays.

The overlays were placed on the same day, within a few hours of each other. A tack coat was applied prior to placement. The 90 mm layers were placed in two lifts of 45 mm and a tack coat was applied between lifts. The preliminary as-built air-void contents for each section, based on cores taken outside of the HVS sections prior to HVS testing are listed in Table 2.3.

Table 2.3: Air void Contents

Section	Mix	Air void content (%)	
		Average for section	Standard deviation
580RF and 586RF	MB15-G	5.1	1.7
581RF and 587RF	RAC-G	8.8	1.3
582RF and 588RF	AR4000-D	7.1	1.5
583RF and 589RF	MB4-G (45mm)	6.5	0.6
584RF and 590RF	MB4-G (90mm)	6.5	0.6
585RF and 591RF	MAC15-G	4.9	1.0

2.6. Summary of HVS Testing

Phase 2 HVS testing is discussed in a series of first-level analysis reports (4-10).

2.6.1 Test Section Failure Criteria

Failure criteria for HVS testing were set as follows:

- Rutting study:
 - Maximum surface rut depth of 12.5 mm (0.5 in) or more
- Reflective cracking study:
 - Cracking density of 2.5 m/m² (0.76 ft/ft²) or more, and/or
 - Maximum surface rut depth of 12.5 mm (0.5 in) or more.

2.6.2 Environmental Conditions

In the rutting study, the pavement surface temperature was maintained at 50°C±4°C (122°F±7°F) in order to assess the susceptibility of the mixes to early rutting under typical pavement temperatures. In the reflective cracking study, the pavement surface temperature was maintained at 20°C±4°C (68°F±7°F) for the first one million repetitions to minimize rutting in the asphalt concrete and to accelerate fatigue damage. Thereafter, the pavement surface temperature was reduced to 15°C±4°C (59°F±7°F) to further accelerate fatigue damage. A temperature control chamber (11) was used to maintain the test temperatures.

The pavement surface received no direct rainfall as it was protected by the temperature control chamber. The sections were tested during both wet and dry seasons and hence water infiltration into the pavement from the side drains and through the raised groundwater table was possible at certain stages of the testing.

2.6.3 Test Duration

HVS trafficking on each section was initiated and completed as shown in Table 2.4.

Table 2.4: Test duration for Phase 2 HVS testing

Phase	Section	Mix	Start Date	Finish Date	Repetitions
Rutting	580RF	MB15-G	09/29/03	10/01/03	2,000
	581RF	RAC-G	09/15/03	09/19/03	7,600
	582RF	AR4000-D	09/04/03	09/09/03	18,564
	583RF	MB4-G (45mm)	12/08/03	12/16/03	15,000
	584RF	MB4-G (90mm)	11/13/03	11/26/03	34,800
	585RF	MAC15-G	10/10/03	10/20/03	3,000
Reflective cracking	586RF	MB15-G	05/25/06	11/21/06	2,492,387
	587RF	RAC-G	03/15/05	10/10/05	2,024,793
	588RF	AR4000-D	11/02/05	04/11/06	1,410,000
	589RF	MB4-G (45mm)	06/23/04	02/08/05	2,086,004
	590RF	MB4-G (90mm)	01/13/04	06/16/04	1,981,365
	591RF	MAC15-G	01/10/07	06/25/07	2,554,335

2.6.4 Loading Program

The HVS loading program for each section is summarized in Table 2.5. Test configurations were as follows:

- In the rutting tests, all trafficking was carried out with a dual-wheel configuration, using radial truck tires (Goodyear G159 - 11R22.5- steel belt radial) inflated to a pressure of 720 kPa, in a channelized, uni-directional loading mode.
- In the reflective cracking tests, all trafficking was carried out with a dual-wheel configuration, using radial truck tires (Goodyear G159 - 11R22.5- steel belt radial) inflated to a pressure of 720 kPa, in a bi-directional loading mode. Lateral wander over the one-meter width of the test section was programmed to simulate traffic wander on a typical highway lane.

Table 2.5: Summary of HVS Loading Program

Phase	Section	Start repetition	Total repetitions	Wheel load (kN)		ESALs	Traffic index
				Planned	Actual*		
Rutting	580RF	Full test	2,000	40	60	11,000	N/A
	581RF		7,600			42,000	N/A
	582RF		18,564			102,000	N/A
	583RF		15,000			83,000	N/A
	584RF		34,800			191,000	N/A
	585RF		3,000			17,000	N/A
* The loading program differs from the original test plan due to an incorrect hydraulic control system setup on loads less than 65 kN in the Phase 1 experiment. The loading pattern from the Phase 1 experiment was thus retained to facilitate comparisons of performance between all tests in the Reflective Cracking Study.							
40 kN - 9,000 lb				60 kN - 13,500 lb			

Table 2.5: Summary of Load History (cont)

Phase	Section	Start repetition	Total repetitions	Wheel load (kN)		ESALs	Traffic index
				Planned	Actual*		
Reflective cracking	586RF (MB15-G)	0 215,000 410,000 1,000,001	2,492,387	40 60 80 100	60 90 80 100	88 million	15
	587RF (RAC-G)	0 215,000 410,000 1,000,001	2,024,793	40 60 80 100	60 90 80 100	66 million	15
	588RF (AR4000-D)	0 215,000 410,000 1,000,001	1,410,000	40 60 80 100	60 90 80 100	37 million	14
	589RF (45mm MB4-G)	0 215,000 407,197 1,002,000	2,086,004	40 60 80 100	60 90 80 100	69 million	15

	591RF (MAC15-G)	0 215,000 410,000 1,000,001	2,554,335	40 60 80 100	60 90 80 100	91 million	15
* The loading program differs from the original test plan due to an incorrect hydraulic control system setup on loads less than 65 kN in the Phase 1 experiment. The loading pattern from the Phase 1 experiment was thus retained to facilitate comparisons of performance between all tests in the Reflective Cracking Study. ** 590RF was the first HVS test on the overlays, and the 60 kN loading pattern was retained for an extended period to prevent excessive initial deformation (rutting) of the newly constructed overlay.							
40 kN - 9,000 lb		60 kN - 13,500 lb	80 kN - 18,000 lb	90 kN - 20,200 lb	100 kN - 22,500 lb		

3. FORENSIC INVESTIGATION SUMMARY

This chapter provides a summary of the observations and measurements recorded during the forensic investigation of Phase 2 of the Reflective Cracking study. Interpretation of the data in terms of pavement performance will be discussed in a separate second-level analysis report.

3.1. Forensic Investigation Procedure

The forensic investigation included the following components:

- Test pit demarcation and excavation
- Test pit profile (Section 3.2)
- Test pit description and photographs (Section 3.3 [Rutting study] and Section 3.4 [Fatigue study])
- Density and moisture content determination (Section 3.4)
- Dynamic Cone Penetrometer (DCP) measurements (Section 3.5)
- Visual assessment of the slab and cores removed from the slab (Section 3.6)
- Scanning Electron Microscope assessment of base materials (Section 3.7)

A total of 18 test pits were excavated for the study, one test pit on each rutting section (between Stations 6 and 8 [see Figure 2.2]) and two test pits on each reflective cracking section (between Stations 4 and 6 and between Stations 10 and 12). The pits were excavated approximately 200 mm into the subgrade below the base. The order of the investigation tasks was as follows:

1. Demarcate the pit;
2. Saw the asphalt concrete;
3. Remove the slab;
4. Determine the wet density of the base (nuclear density gauge);
5. Determine the in situ strength of the base and subgrade (Dynamic Cone Penetrometer);
6. Remove the base material and top 200 mm of the subgrade;
7. Sample material from the top 150 mm and bottom 150 mm of the base, and from the subgrade for moisture content determination
8. Measure layer thicknesses;
9. Describe the profile;
10. Photograph the profile;
11. Sample additional material from the profile if required, and
12. Reinstall the pit.

The following additional information is relevant to the investigation:

- The procedures for HVS test section forensic investigations, detailed in the document entitled *Quality Management System for Site Establishment, Daily Operations, Instrumentation, Data Collection and Data Storage for APT Experiments* (12) were followed.
- The saw cuts were made at least 50 mm into the base to ensure that the slab could be removed from the pit without it breaking.
- Nuclear density measurements were taken between the test section centerline and inside (traffic side) edge of the test section. Two readings were taken, the first with the gauge aligned with the direction of trafficking and the second at 90° to the first measurement (Figure 3.1).
- DCP measurements were taken between the test section centerline and inside (traffic side) edge of the test section, and between the edge of the test section and the edge of the test pit on the traffic side (Figure 3.1). A third DCP measurement was taken if inconsistent readings were obtained.
- Layer thicknesses were measured from a leveled reference straightedge above the pit. This allowed the camber of the section to be included in the profile. Measurements were taken across the pit at 50-mm intervals.

3.2. Test Pit Profiles

Test pit profile illustrations are provided in Appendix A. Average measurements from the profile are listed in Tables 3.1 and 3.2.

Table 3.1: Average Layer Thicknesses from Rutting Study Test Pit Profiles

	Section	Layer	Average (mm)	Std. Deviation (mm)	Minimum (mm)	Maximum (mm)

3.3. Rutting Study Test Pit Observations

3.3.1 Section 580RF: 45 mm MB15-G

Observations from the Section 580RF test pit (Figure 3.2) include:

- The overlay thickness was considerably less than the design (average 37 mm), while the average thickness of the underlying DGAC was marginally less (86 mm) than the design.

- Some densification (approximately 3 to 4 mm) was noted in the overlay in the trafficked area. Most of the rutting occurred in the underlying DGAC layer (Figure 3.3). No rutting was noted in the base and subgrade. Some displacement was recorded on either side of the trafficked area.
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.
- Apart from rutting, no other distresses were noted in the asphalt layers.
- The base under the trafficked area was thinner than the design (average 387 mm), but met the design requirements (410 mm) on the shoulder side of the section. The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including andesite, granite, quartz, and quartzite pebbles) and small quantities of glass, fabric, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as hard in the top 70 mm, very hard between 70 mm and 250 mm, and firm to hard below as moisture content increased (Figures 3.4 and 3.5).
- Recementation of the base material was visibly apparent. A cement odor was present and strong effervescence was noted when dilute hydrochloric acid was sprayed onto the base material, indicating the presence of old cement (Figure 3.6). When phenolphthalein was sprayed onto the base material, the sprayed area turned red, signifying a pH greater than 10, which is indicative of uncarbonated cemented material (Figures 3.6 and 3.7). These tests, together with the DCP measurements discussed in Section 3.6 indicate some recementation of the recycled concrete base material occurred after construction. This is discussed in more detail in Section 3.7.
- Moisture content in the base was rated as dry-to-moist. The material appeared drier than the pits on the other sections.
- The layer definition between the base and subgrade was clear. No punching of the base into the in situ material was noted.
- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

Figure 3.6: 580RF phenolphthalein and hydrochloric acid reaction on base material.

Figure 3.7: 580RF phenolphthalein reaction.

3.3.2 Section 581RF: 45 mm RAC-G

Observations from the Section 581RF test pit (Figure 3.8) include:

- The overlay was considerably thicker than the design (average 56 mm), while the average thickness of the underlying DGAC was less than the design (average 79 mm).
- Some densification (approximately 2 to 3 mm) was noted in the overlay in the trafficked area. Most of the rutting occurred in the DGAC layer (Figure 3.9). No rutting was recorded in the base and subgrade. Some displacement was recorded on either side of the trafficked area.
- The overlay was well bonded to the DGAC in the trafficked area, but some debonding was noted on the edge of the pit. Poor bonding was also noted between the two lifts in the DGAC in some areas. Water from the saw cutting operation was still clearly visible in these poorly bonded areas after the rest of the profile had dried (Figure 3.10). The DGAC was well bonded to the aggregate base.
- Some segregation was noted in the DGAC layer on the traffic side of the section (Figure 3.10). Apart from this and the rutting, no other distresses were noted in the asphalt layers.
- The base under the trafficked area was thinner than the design (average 373 mm). Two distinct layers were noted in the base and although the material appeared to be from the same source, the lower layer was far wetter and appeared to have a weaker structure (Figure 3.11). This layer was designated as a selected layer in the profile assessment. The material in the two layers was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including andesite, chert, phyllite, quartz, and quartzite pebbles) and small quantities of glass, fabric, metal, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as hard in the top 50 mm, very hard between 50 and 250 mm, and hard to firm in the selected layer as moisture content increased and structure changed (Figures 3.12 and 3.13).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base and selected layer was rated as moist and moist-to-wet, respectively.
- The layer definition between the base, selected layer, and subgrade was clear. No punching of the selected layer into the in situ material was noted.
- The subgrade was moist, dark brown clay with medium to high plasticity. Some mottling was observed. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

Figure 3.13: 581RF test pit profile. (3)

3.3.3 Section 582RF: 90 mm AR4000-D

Observations from the Section 582RF test pit (Figure 3.14) include:

- The average thicknesses of the overlay (101 mm) and underlying DGAC (97 mm) were greater than the design.
- Rutting was noted in both the overlay and the underlying layer (Figure 3.15). No rutting was noted in the base and subgrade. Slight displacement was recorded on either side of the trafficked area.
- The overlay was generally poorly bonded to the underlying layer. Bonding between lifts was also unsatisfactory. Water from the saw cutting operation was still clearly visible in these poorly bonded areas after the rest of the profile had dried (Figure 3.16). The DGAC was well bonded to the aggregate base.
- Some segregation was noted in the underlying DGAC layer on the traffic side of the section (Figure 3.16). Apart from this and the rutting, no other distresses were noted in the asphalt layers.
- The base under the trafficked area was marginally thinner (average 394 mm) than the design. The material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including chert, quartzite pebbles, and basalt) and small quantities of glass, fabric, metal wire, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as hard in the top 100 mm, very hard between 100 and 300 mm, and hard below 300 mm (Figure 3.17).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. Some punching of the base material into the in situ material was noted.
- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was noted. Consistency was rated as hard and structure as slickensided. Some organic matter was present. No hydrochloric acid or phenolphthalein reaction was recorded on the subgrade material.

Figure 3.17: 582RF test pit profile. (2)

3.3.4 Section 583RF: 45 mm MB4-G

Observations from the Section 583RF test pit (Figure 3.18) include:

- The average thickness of the overlay matched the design thickness, although measurements indicated that thickness tapered over the width of the test pit (51 mm to 39 mm). The average thickness of the underlying DGAC was considerably less (77 mm) than the design and also tapered from one side of the pit to the other (103 mm to 61 mm).
- Some densification (approximately 4 to 5 mm) was noted in the wheelpaths in the overlay. Most of the rutting occurred in the DGAC layer (Figure 3.19). No rutting was noted in the base and subgrade. Severe displacement was recorded on the shoulder side of the trafficked area and in between the wheelpaths (Figure 3.19).
- The overlay was well bonded to the DGAC although some shearing was noted on the bond between the overlay and DGAC in the severely heaved areas. The DGAC was well bonded to the aggregate base.

- Apart from rutting, no other distresses were noted in the asphalt layers.
- The base was thinner (average 361 mm) than the design across the full width of the test pit. The base material was dark grey-brown and consisted primarily of non-plastic, recycled construction rubble, which included various types of natural aggregate (including quartz, quartzite pebbles, phyllite, and andesite) and small quantities of glass, fabric, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as very hard in the top 220 mm, and hard to firm below as moisture content increased (Figures 3.20 and 3.21).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. No punching of the base into the in situ material was noted.
- The subgrade was moist, dark brown clay with medium to high plasticity. Some mottling was observed. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded on the subgrade material.

Figure 3.19: 583RF test pit profile. (1)

Figure 3.20: 583RF test pit profile. (2)

Figure 3.21: 583RF test pit profile. (3)

3.3.5 Section 584RF: 90 mm MB4-G

Observations from the Section 584RF test pit (Figure 3.22) include:

- The average thickness of the overlay was marginally greater (94 mm) than the design thickness, while the average thickness of the underlying DGAC was considerably thicker (102 mm).
- Some densification (approximately 4 to 5 mm) was noted in the overlay in the wheelpaths, but most of the rutting occurred in the DGAC layer (Figure 3.23). No rutting was noted in the base and subgrade. Some displacement was recorded on either side of the trafficked area.
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.
- Apart from rutting, no other distresses were noted in the asphalt layers.
- The base under the trafficked area was significantly thinner (average 332 mm) than the design. The base material was dark grey-brown and consisted primarily of non-plastic, recycled construction rubble, which included various types of natural aggregate (including quartz, quartzite pebbles, phyllite, granite, and andesite) and small quantities of glass, fabric, metal (nails and wire), and some organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as very hard in the top 200 to 250 mm, and hard to firm below that as moisture content increased (Figures 3.24 and 3.25).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear but rather uneven. Some punching of the base into the in situ material was also noted.

- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was observed. Consistency was rated as hard and structure as slickensided. Some organic matter was present. No hydrochloric acid or phenolphthalein reaction was recorded on the subgrade material.

Figure 3.22: 584RF test pit location.

Figure 3.23: 584RF test pit profile. (1)

Figure 3.25: 584RF test pit profile. (3)

3.3.6 Section 585RF: 45 mm MAC15-G

Observations from the Section 585RF test pit (Figure 3.26) include:

- The average thickness of the overlay matched the design thickness, although measurements indicated that thickness tapered over the width of the test pit (35 mm to 50 mm). The average thickness of the underlying DGAC was considerably thicker (110 mm) than the design and also tapered from one side of the pit to the other (101 mm to 127 mm).
- Minor densification (approximately 1 to 2 mm) was noted in the overlay in the wheelpaths, with most of the rutting occurring in the DGAC layer (Figure 3.27). No rutting was noted in the base and subgrade. Some displacement was recorded on either side of the trafficked area.

- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.
- Apart from rutting, no other distresses were noted in the asphalt layers.
- The base under the trafficked area met the design thickness. The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including quartz, quartzite pebbles, andesite, and granite) and small quantities of glass, fabric, metal (nails and wire), and some organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as very hard in the top 250 mm, and hard to firm below that as moisture content increased (Figures 3.28 and 3.29).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear and no punching of the base into the in situ material was noted.
- The subgrade was moist, to wet dark brown clay with medium to high plasticity. Some mottling was noted. Consistency was rated as hard and structure as slickensided. Some organic matter was present. No hydrochloric acid or phenolphthalein reaction was recorded on the subgrade material.

3.4. Reflective Cracking Study Test Pit Observations

3.4.1 Section 586RF: 45 mm MB15-G

Observations from the Section 586RF test pits (Figure 3.28) include:

- The average thickness of the overlay equaled or exceeded the design thickness (45 mm at Station 12 and 52 mm at Station 4), while the average thickness of the underlying DGAC was less than the design (76 mm and 81 mm at Stations 4 and 12, respectively).
- Very little rutting/densification was evident in the overlay. Rutting in the underlying DGAC from the Phase 1 trafficking was noted in both test pits (Figures 3.29 and 3.30). No rutting was noted in the base and subgrade. No displacement was recorded on either side of the trafficked area.
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base (Figure 3.31).
- Bottom-up cracking was noted in the DGAC layer in both test pits (Figure 3.32). No propagation of the cracks into the overlay was observed, however, this could be attributed to resealing of any cracks when the overlay was heated during sawing and excavation of the test pit. No other distresses were noted in the asphalt concrete layers.
- The average thickness of the base was marginally less than the design (average 400 mm to 406 mm), but exceeded the design requirements on the shoulder side of the section (415 mm to 425 mm). The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (predominantly quartz and quartzite pebbles) and small quantities of brick, glass, fabric, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as hard in the top 180 mm, very hard

between 180 mm and 290 mm, and firm to hard below as moisture content increased (Figure 3.33). The DCP did not penetrate the trafficked area of the test pit at Station 12.

- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. No punching of the base into the in situ material was noted.
- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

Figure 3.32: 586RF cracks in underlying DGAC.

Figure 3.33: 586RF strongly cemented base.

3.4.2 Section 587RF: 45 mm RAC-G

Observations from the Section 587RF test pits (Figure 3.34) include:

- The average thickness of the overlay in both test pits equaled the design thickness, while the average thickness of the underlying DGAC was less than the design (81 mm and 83 mm at Stations 4 and 12 respectively).
- Although a rut was measured on the surface, very little rutting/densification was evident in the overlay in either test pit. Most rutting occurred in the underlying DGAC. The rut resulting from Phase 1 HVS trafficking (see Section 1.2) could not be distinguished from that resulting from Phase 2 trafficking at Station 4 (Figure 3.35). However, at Station 12, where less rutting was recorded during Phase 2 HVS testing, the rut from earlier trafficking was observed (Figure 3.36). A small rut (2 mm to 4 mm) was measured in the base across the width of the trafficked section in both test pits. No rutting was observed in the subgrade. Some displacement was recorded on both sides of the trafficked area.
- The overlay was well bonded to the DGAC in the trafficked area, but some debonding was noted on the edge of the test pit at Station 4. Poor bonding was also noted between the two lifts in the DGAC in some areas. The DGAC was well bonded to the aggregate base.
- Bottom-up cracking was noted in the DGAC and overlay in the test pit at Station 4 (Figure 3.37). No cracks were observed in the asphalt concrete at Station 12 (Figure 3.38). No other distresses were noted in the asphalt concrete.
- The average thickness of the base was considerably less than the design (average 325 mm to 332 mm). As noted in the Section 581RF test pit, two distinct layers were observed in the base with the material in the lower layer appearing wetter and weaker than the upper layer. The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including quartz, quartzite pebbles, phyllite,

and granite) and small quantities of brick, glass, fabric, wood chips, and other organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. At Station 4, consistency was rated as hard in the top 200 mm and hard to firm below (Figure 3.33), with the DCP penetrating the layer relatively easily. At Station 12, DCP penetration was slower with consistency rated as hard in the top 40 mm of material, very hard between 40 mm and 240 mm, and hard to firm towards the subgrade.

- Recementation of the base material was visibly apparent in both test pits, although bond strengths appeared weaker in the test pit at Station 4. On this pit face, a strong hydrochloric acid reaction, and a moderate phenolphthalein reaction were recorded (with pink indicating a pH of between 8.4 and 10 [attributed to possible carbonation of the cemented layer or to weak cementation]). At Station 12, strong hydrochloric acid and phenolphthalein reactions were recorded.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. No punching of the base into the in situ material was noted.
- The subgrade was moist, to wet dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

Figure 3.41: 587RF#12 areas of strong and weak base cementation.

3.4.3 Section 588RF: 90 mm AR4000-D

Observations from the Section 588RF test pits (Figure 3.42) include:

- The average thicknesses of the overlay and underlying DGAC in both test pits were close to the design thickness (89 mm and 93 mm for the overlay and 92 mm and 89 mm for the underlying layer).
- Rutting was noted in both the overlay and the underlying layer (Figures 3.43 and 3.44). Some rutting was also measured at the top of the base in the test pit at Station 12. No rutting was observed in the subgrade. Displacement was recorded on either side of the trafficked area. The rut resulting from Phase 1 trafficking could not be clearly distinguished from that resulting from Phase 2 trafficking.
- The overlay was generally poorly bonded to the underlying layer (Figure 3.45). Bonding between lifts was also unsatisfactory (Figure 3.46). Water from the saw cutting operation was still clearly visible in these poorly bonded areas after the rest of the profile had dried. The DGAC was well bonded to the aggregate base.
- Bottom-up cracking was noted in the underlying DGAC and in the overlay in both test pits. Some of the cracks originated at the bottom of the underlying DGAC and continued all the way to the surface (Figure 3.44), while some appeared to have stopped at the bond between the two lifts of the overlay. A few bottom-up cracks originating from the weak bond between the overlay and the underlying layer and between the overlay lifts were also noted (Figure 3.47). Some segregation was noted in the underlying DGAC layer (Figure 3.46).
- The average thickness of the base was considerably less (364 mm and 348 mm for the two test pits) than the design. The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including quartz, quartzite pebbles, phyllite, basalt, and granite) and small quantities of brick, glass, fabric, wood chips and other organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. At Station 4, consistency was rated as hard in the top 100 mm, as very hard between 100 mm and 200 mm, as hard between 200 and 260 mm, and as hard to firm below 260 mm. At Station 12, consistency was rated as hard in the top 60 mm of material, very hard between 60 mm and 250 mm, and hard to firm below.
- Recementation of the base material was visibly apparent in both test pits, although bond strengths appeared weaker in the test pit at Station 12 (Figure 3.48) compared to the material at Station 4 (Figure 3.49). Relatively strong hydrochloric acid and phenolphthalein reactions were recorded in both test pits.
- Moisture content in the base was rated as moist.

- The layer definition between the base and subgrade was clear. Some punching of the base into the in situ material was noted.
- The subgrade was moist, to wet dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

3.4.4 Section 589RF: 45 mm MB4-G

Observations from the Section 589RF test pits (Figure 3.50) include:

- The average thickness of the overlay generally equaled the design thickness, while the average thickness of the underlying DGAC was considerably less than the design (84 mm and 75 mm at Stations 4 and 12 respectively).
- Very little rutting/densification was evident in the overlay. Rutting in the underlying DGAC from the Phase 1 trafficking was noted in the Station 4 profile (Figure 3.51), but no rutting was noted in the base and subgrade on this profile. At Station 12, the severe rutting observed occurred predominantly in the underlying DGAC layer, with some rutting in the base and only minor densification in the overlay (Figure 3.52). No rutting was recorded in the subgrade. Severe displacement was recorded on either side of the trafficked area at the Station 12 test pit (Figure 3.53).
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.

- Bottom-up cracking was noted in the DGAC layer in both test pits. No propagation of the cracks into the overlay was observed. However, this could be attributed to resealing of any cracks when the overlay was heated during sawing and excavation of the test pit. No other distresses were noted in the asphalt concrete layers.
- The average thickness of the base was less than the design (average 362 mm to 385 mm). The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (predominantly basalt, andesite, quartz and quartzite pebbles) and small quantities of brick, glass, fabric, and organic matter. The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. The material from the test pit at Station 12 appeared coarser than in other pits (Figures 3.54 and 3.55). Consistency was rated as very hard in the top 250 mm, hard between 250 mm and 290 mm, and hard to firm below as moisture content increased.
- Recementation of the base material was visibly apparent. A cement odor was present and moderate hydrochloric acid and phenolphthalein reactions were noted in some areas.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. Some punching of the base material into the subgrade was observed.
- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

Figure 3.54: 589RF#4 base material.

Figure 3.55: 589RF#12 base material (coarser than other pits).

3.4.5 Section 590RF: 90 mm MB4-G

Observations from the Section 590RF test pits (Figure 3.56) include:

- The average thickness of the overlay varied between 86 mm (Station 4) and 94 mm (Station 12). The average thickness of the underlying DGAC was considerably less than the design (average of 81 mm in both test pits).
- Very little rutting/densification was recorded on the section, with most occurring in the underlying DGAC (Figures 3.57 and 3.58). Rutting in the underlying DGAC from the Phase 1 trafficking was noted in the Station 12 profile (Figure 3.58). No significant displacement was measured and no rutting was noted in the base and subgrade.
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.
- Bottom-up cracking was noted in the DGAC layer in both test pits (Figure 3.59). No propagation of the cracks into the overlay was observed, however, this could be attributed to resealing of any

cracks when the overlay was heated during sawing and excavation of the test pit. No other distresses were noted in the asphalt concrete layers.

- The average thickness of the base was less than the design (average 359 mm to 366 mm). The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (predominantly basalt, andesite, quartz and quartzite pebbles) and small quantities of brick, glass, fabric, and organic matter (Figures 3.60 and 3.61). The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as very hard in the top 200 mm, as hard between 200 mm and 220 mm, and as firm below.
- Recementation of the base material was visibly apparent. A cement odor was present and moderate hydrochloric acid and phenolphthalein reactions were noted in some areas.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. Some punching of the base material into the subgrade was observed.
- The subgrade was moist, dark brown clay with medium to high plasticity. Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

3.4.6 Section 591RF: 45 mm MAC15-G

Observations from the Section 591RF test pits (Figure 3.62) include:

- The average thickness of the overlay was slightly thicker than the design (51 mm at Station 4 and 49 mm at Station 12), while the average thickness of the underlying DGAC was considerably less than the design (72 mm and 80 mm at Stations 4 and 12 respectively).
- Very little rutting/densification was evident in the overlay. Rutting in the underlying DGAC from Phase 1 trafficking was noted in both test pits (Figures 3.63 to 3.65). Some rutting, attributed to Phase 1 trafficking, was noted at the top of the base in both test pits. No rutting was observed in the subgrade and no displacement was recorded on either side of the trafficked area.
- The overlay was well bonded to the DGAC, which was well bonded to the aggregate base.

- Bottom-up cracking was noted in the DGAC layer in both test pits (Figure 3.66). No propagation of the cracks into the overlay was observed. However, this could be attributed to resealing of any cracks when the overlay was heated during sawing and excavation of the test pit. No other distresses were noted in the asphalt concrete layers.
- The average thickness of the base was considerably less than the design (average 325 mm and 333 mm for the two test pits, respectively). The base material was dark grey-brown and consisted primarily of non-plastic recycled construction rubble, which included various types of natural aggregate (including andesite, phyllite, quartz and quartzite pebbles) and small quantities of brick, glass, wire, fabric, and organic matter (Figure 3.67). The structure was generally homogenous. Grain size varied from fine to coarse with maximum particle size typically between 19 mm and 25 mm. Consistency was rated as hard to very hard in the top 200 mm, and hard below that (Figure 3.68).
- Recementation of the base material was visibly apparent. A cement odor was present and strong hydrochloric acid and phenolphthalein reactions were noted.
- Moisture content in the base was rated as moist.
- The layer definition between the base and subgrade was clear. Some punching of the base into the in situ material was noted (Figure 3.68).
- The subgrade was moist, dark brown clay with medium to high plasticity. Some punching of aggregate from the base was recorded (Figure 3.69). Mottling was evident. Consistency was rated as hard and structure as slickensided. Some organic matter was noted. No hydrochloric acid or phenolphthalein reaction was recorded.

3.5. Density and Moisture Content

Table 3.3 (rutting study) and Table 3.4 (reflective cracking study) summarize the density and moisture content measurements on each section. The tables include wet and dry density and moisture content of the base as measured with a nuclear gauge, the laboratory determined gravimetric moisture content of the base (average of two samples from the top and bottom of the excavated base), the subgrade laboratory determined gravimetric moisture content (sample removed from the bottom of the test pit, approximately 200 mm below the bottom of the base), and the recalculated dry density of the base (using the gravimetric moisture content). The gauge measurements are an average of two readings taken in the pit (see Figure 3.1).

		200	2,242	10.5	2,030			

* Recalculated dry density using gauge wet density and laboratory gravimetric moisture content.

Densities were generally consistent throughout the section. Nuclear gauge determined wet densities ranged between 2,111 kg/m³ and 2,241 kg/m³ for the 18 test pits (average 2,176 kg/m³, standard deviation 34 kg/m³). This corresponds with the average wet density of 2,200 kg/m³ for the road base recorded after construction. The average nuclear gauge determined dry density was 1,956 kg/m³ with a standard deviation of 44 kg/m³. The lowest dry density recorded was 1,879 kg/m³ (582RF) and the highest was 2,017 kg/m³ (587RF).

Nuclear gauge determined moisture contents, measured at four intervals in the top 200 mm of the base, averaged 11.1 percent (standard deviation of 1.1 percent) for the 18 test pits. The highest moisture content measured was 14.4 percent (590RF, Station 4 at 150 mm depth), while the lowest was 8.7 percent (580RF, at 100 mm depth). In most test pits, the moisture content in the upper 50 mm was on the order of one percent higher than in the material between 150 mm and 200 mm. The optimum moisture content of the Class II aggregate base material, determined prior to construction, was 8.9 percent, somewhat lower than the average recorded with the nuclear gauge.

Laboratory-determined gravimetric moisture contents varied between 6.9 percent and 9.2 percent, with an average of 8.7 percent. The laboratory-determined moisture contents were on average 2.0 percent lower (between 0.9 and 4.4 percent) than that recorded by the nuclear gauge, and were therefore more consistent with the optimum moisture content of the material. The higher moisture contents determined with the nuclear gauge could be associated with the presence of some excess moisture from the saw cutting operation during pit excavation. Recalculated dry densities, determined using the gauge wet density and gravimetric moisture content, were therefore higher than the gauge determined dry densities.

Subgrade densities were not measured. The average subgrade moisture content was 15 percent (lowest of 12.9 percent, and highest of 18.0 percent), considerably higher than the base moisture content. The presence of mottling in the subgrade material indicates that the moisture content probably fluctuated seasonally.

3.6. Dynamic Cone Penetrometer

Dynamic Cone Penetrometer (DCP) analysis plots for the trafficked and untrafficked areas from each test pit are provided in Appendix B. A summary of the results is provided in Tables 3.5 and 3.6.

¹ DCP Structure Number (number of blows to 800 mm) ² Unconfined compressive strength ³ Elastic modulus											

The DCP Structure Number (DSN_{800}) is the total number of blows needed to penetrate 800 mm into the pavement structure and is used as a quick indicator of the overall pavement strength. A summary of this parameter from the 18 test pits is provided in Table 3.7.

Table 3.7: Summary of DSN800 Analysis

Sample	DCP Location	Average	Standard Deviation	Lowest	Highest
All pits	All	212	50	138	337
All pits	Trafficked	205	56	138	337
	Untrafficked	219	44	149	298
Pits on rutting sections	All	200	43	149	281
Pits on cracking sections	All	222	54	138	337
Pits on rutting sections	Trafficked	195	47	156	281
	Untrafficked	205	42	149	271
Pits on cracking sections	Trafficked	214	66	138	337
	Untrafficked	230	45	135	298

The summary results indicate that the trafficked areas were marginally stronger than the untrafficked areas and that the reflective cracking sections were marginally stronger than the rutting sections. This is probably attributed to the higher number of load repetitions on the sections and the associated densification of the material. It is interesting to note that the weakest section (588RF at Station 12) was also the area with the most cracking on completion of testing.

Further analysis of the results indicate the presence of a weaker area at the top of the base (upper 30 to 90 mm) and an even weaker area at the bottom of the base. This is consistent with observations in the pits. The weak upper layer could be attributed to poor compaction, to crushing under HVS loading, or a combination of the two. It is not attributed to carbonation of the recemented layer, based on the results of phenolphthalein tests in the pits. The weak area at the bottom of the base is attributed to poor compaction associated with the poor support provided by the relatively weak subgrade.

The DCP-derived Unconfined Compressive Strength (UCS) and elastic modulus are consistent with measurements on highways around the state.

3.7. Assessment of Cores

3.7.1 Visual Assessment

Up to 20 cores were sampled from the trafficked area on each section, including eight cores from each test pit slab. These cores were obtained to gain a better understanding of where the crack initiated, the crack path, where the crack it terminated, and how far cracks continued into the overlays. Each core was

cleaned and then scrutinized for cracks. Photographs of the cores from each section are shown in Figures 3.70 to 3.76. Cracks have been highlighted. If no cracks were observed on the sides or bottom and top faces, the core was split in a similar manner to an indirect tensile test to determine whether it would break on a weak plane caused by the presence of a crack.

Figure 3.70: MB15-G: Cracks on core.

Figure 3.71: RAC-G: Cracks on core.

Figure 3.72: RAC-G: Highlighted reflected crack through both layers.

Figure 3.73: AR4000-D: Cracks on core.

Figure 3.74: 45 mm MB4-G: Cracks on core.

Figure 3.75: 90 mm MB4-G: Cracks on core..

Figure 3.76: MAC15-G: Cracks on core.

Very little information on cracking patterns was obtained from this assessment. This was attributed to a number of factors including the sealing of cracks with melted rubber during the coring process. Reflected cracks were only clearly distinguishable on the AR4000-D and RAC-G cores. These cracks all appeared to have initiated close to the bottom of the underlying DGAC layer and then propagated through to the surface (Figures 3.71 to 3.73). No cores were retrieved from the severely cracked area of Section 588RF (AR4000-D), because the test pit slab disintegrated when it was handled. No conclusions could be drawn regarding the depth (if any) that cracks had reflected through into those overlays that did not crack after HVS testing (i.e., MB4-G, MB15-G and MAC15-G).

3.7.2 Final Air-Void Content

The air-void contents of the trafficked reflective cracking sections were determined from cores removed from each section during the forensic investigation. Results are summarized in Table 3.8.

Table 3.8: Summary of Air-Void Contents after HVS Testing

Section	Overlay	Number of Cores	Air-Void content (%)					
			Average		Std. Dev		Lowest	Highest
			After	(Before) ¹	After	(Before) ¹		
586RF	MB15-G	16	3.8	(5.1)	1.5	(1.7)	2.2	6.8
587RF	RAC-G	13	4.0	(8.8)	1.6	(1.3)	2.3	7.0
588RF	AR4000-D	21	6.5	(7.1)	1.6	(1.5)	3.3	9.4
589RF	45 mm MB4-G	10	2.9	(6.5)	1.2	(0.6)	1.5	5.2
590RF	90 mm MB4-G	15	1.9	(6.5)	0.7	(0.6)	0.8	3.6
591RF	MAC15-G	12	2.7	(4.9)	1.5	(1.0)	3.2	8.0
¹ Before HVS testing, included for comparison. Cores taken outside HVS section.								

The results show that the air-void content decreased after HVS trafficking on all sections except Section 591RF. It is not clear why the air-void content on Section 591RF increased, although it could be attributed to the first set of cores being taken from outside of the section (closer to the edge of the road), which may have had a slightly higher compaction. The largest change was recorded on Section 590RF and the smallest on Section 588RF. Variability along and across the section was relatively high, this being attributed to the programmed wander pattern of the HVS, which applies more passes in the center portion of the section compared to the edges.

3.8. Microscope Study

3.8.1 Background and Objectives

Samples removed from the test pits in Section 591RF were assessed using optical and scanning electron (SEM) microscopes in an attempt to determine whether the cementation of the base material resulting from vestigial cement generated during breaking up and processing had occurred. No additional cement was added during construction of the test track. It should be noted that this was only a very brief investigation and that a more thorough exercise on a wider spectrum of samples might reveal additional information.

Various components of the pavement were investigated using a number of samples. Two samples are discussed below:

- Sample 1: Intact base material matrix, and
- Sample 2: Intact base material matrix after exposure to atmospheric air for 10 days.

3.8.2 Observations

Sample 1

This material was the essentially uncarbonated matrix material. Figure 3.77 shows the overall view at a magnification of about 60 times.

Figure 3.77: General SEM view of Sample 1 at $\pm 60x$ magnification.

The material was generally intact and showed mostly particles of about $100\ \mu\text{m}$ diameter within a cemented matrix. At a greater magnification (Figure 3.78 [optical microscope with $\pm 200x$ magnification] and Figure 3.79 [SEM with $\pm 600x$ magnification]), definite interlocking needle-like crystals can be identified in fragments of the original stabilized material. These are typical of the cementitious products in old, well-stabilized road materials. Closer examination showed that some subsequent (i.e. after construction) crystal development had also occurred.

Figure 3.78: Optical microscope view ($\pm 200x$) of Sample 1.

Figure 3.79: SEM view ($\pm 600x$) of Sample 1.

Sample 2

Sample 2 was exactly the same as Sample 1 except that the specimen was exposed to atmospheric carbon dioxide prior to preparation for the microscope studies. The overall effect is shown in Figure 3.80 (optical microscope at $\pm 100\times$ magnification) and Figure 3.81 (SEM at $\pm 55\times$ magnification), in which significant cracking is visible. This is the typical result of carbonation where the development of calcite (calcium carbonate, CaCO_3) from lime (calcium hydroxide, Ca(OH)_2) in the material results in expansion and cracking of the material. Such cracking is unlikely to result from drying as it was not seen in the uncarbonated specimen, which was also dried, albeit under slightly different conditions. Figure 3.82 (optical microscope at $\pm 100\times$ magnification), Figure 3.83 (optical microscope at $\pm 200\times$ magnification), and Figure 3.84 (SEM at $\pm 140\times$ magnification) show the presence of calcite crystals associated with the cracking in the carbonated sample, none of which were evident in the uncarbonated material. The well-crystallized nature of the material is indicative of recent formation (during the week before examination). There was also a conspicuous absence of calcium hydroxide, indicating severe carbonation.

Figure 3.83: Optical microscope view ($\pm 200\times$) of calcite crystal development associated with cracks.

Figure 3.84: SEM view ($\pm 140\times$) of calcite crystal development associated with cracks.

3.9. Second-Level Analysis

A second-level analysis report will be prepared on completion of all HVS testing, laboratory testing, and data analysis. This report will include:

- Comparison of performance between test sections;
- Comparisons of HVS test results with laboratory test results;
- Predicted (mechanistic-empirical) versus actual performance;
- Performance comparison of the overlays with the same underlying support conditions, and
- Simulations using various pavement structures, climatic conditions, traffic volumes, and traffic speeds.

4. CONCLUSIONS

This report follows seven first-level reports that detail the results of HVS testing performed to validate Caltrans overlay strategies for the rehabilitation of cracked asphalt concrete. It describes the findings and observations of the forensic investigation, which included the excavation and assessment of 18 test pits (one on each rutting section and two on each reflective cracking section), nuclear density measurements, Dynamic Cone Penetrometer (DCP) assessments, and a visual assessment of cores. A microscope study was also undertaken to investigate apparent recementation of the base material. Laboratory fatigue and shear studies were conducted in parallel with HVS testing and those results are detailed in separate reports. Comparison of the laboratory and test section performance is discussed in a separate second-level report.

The pavement was designed according to the Caltrans Highway Design Manual Chapter 600 using the computer program *NEWCON90*. Design thickness was based on a subgrade R-value of 5 and a Traffic Index of 7 (~121,000 ESALs). The overlay thickness was determined according to Caltrans Test Method (CTM) 356 using Falling Weight Deflectometer (FWD) deflections.

Findings and observations based on the data collected during this forensic investigation include:

- There was considerable variation in the thicknesses of the base, underlying DGAC, and the overlays over the length and width of the test road.
- In the rutting experiments (Sections 580RF through 585RF), rutting occurred primarily in the underlying DGAC and not in the overlay. In the reflective cracking experiments (Sections 586RF through 591RF), rutting occurred in both layers. Rutting from the Phase 1 trafficking was clearly visible on most test pit profiles. Very little rutting occurred in the base and no rutting was recorded in the subgrade. This corresponds to the Multi-depth Deflectometer permanent deformation analyses discussed in the first-level reports on each section.
- Cracks were observed on some of the test pit profiles. In the underlying DGAC layer, cracks were generally clearly visible. However, in the overlays, heat generated from the saw cut operation appeared to seal any cracks and no conclusions could be drawn as to the depth that cracks had reflected into the overlays. Most cracks appeared to have initiated close to the bottom of the underlying DGAC. Some crack initiation was also observed at poorly bonded joints between lifts and overlays in the AR4000-D section (Section 588RF). No additional information was gathered from an assessment of cores. No cracking was observed in the base.
- Some post-construction cementation of the base material appeared to have occurred. This was substantiated with DCP tests, close inspection of the test pit profile, the use of phenolphthalein to

determine the pH of the base material, and examination of specimens under optical and scanning electron microscopes. This recementation appears to have contributed to the good performance of the sections.

- Densities were generally consistent throughout the section. Nuclear gauge determined wet densities averaged $2,176 \text{ kg/m}^3$ (standard deviation of 34 kg/m^3 [135.8 pcf, standard deviation of 2.1 pcf), which corresponds with the average wet density of $2,200 \text{ kg/m}^3$ (137.3 pcf) for the road base recorded after construction.
- Nuclear gauge determined moisture contents averaged 11.1 percent (standard deviation of 1.1 percent) for the 18 test pits. In most test pits, the moisture content in the upper 50 mm (2 in) was on the order of one percent higher than in the material between 150 mm (6 in) and 200 mm (8 in). The optimum moisture content of the Class II aggregate base material, determined prior to construction, was 8.9 percent, somewhat lower than the average recorded with the nuclear gauge. Laboratory-determined gravimetric moisture contents averaged 8.7 percent, which was closer to the optimum moisture content.
- Subgrade densities were not measured. The average subgrade moisture content was 15 percent (lowest of 12.9 percent, and highest of 18.0 percent), considerably higher than the base moisture content. The presence of mottling in the subgrade material indicates that the moisture content probably fluctuated seasonally.
- The air-void contents of cores removed from the reflective cracking sections after HVS testing were lower compared to those determined from cores removed from outside the sections prior to HVS testing, as expected.

The findings of this investigation confirm the conclusions drawn from analyses of data collected from the instrumentation during HVS testing and documented in the first-level analysis reports.

No recommendations as to the use of the modified binders in overlay mixes are made at this time. These recommendations will be included in the second-level analysis report, which will be prepared and submitted on completion of all HVS and laboratory testing.
